# NATURE

A WEEKLY JOURNAL OF SCIENCE

Volume 205

JANUARY 2, 1965 to MARCH 27, 1965

LONDON

MACMILLAN (JOURNALS), LTD.

NEW YORK: ST. MARTIN'S PRESS, INC.

### DATES and PAGINATION of WEEKLY ISSUES

Serial No.		Date of issue	Pagination
4966	....	January 2	1-112
4967	....	" 9	113-214
4968	....	" 16	215-318
4969	....	" 23	319-424
4970	....	" 30	425-528
4971	....	February 6	529-630
4972	....	" 13	631-728
4973	....	" 20	729-834
4974	....	" 27	835-934
4975	....	March 6	935-1038
4976	....	" 13	1039-1140
4977	....	" 20	1141-1246
4978	....	" 27	1247-1344

R2339

# INDEX

- ABRAMOWITZ, M., and Stegun, I. A. (edited by) : Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, review by Prof. T. A. A. Broadbent, 9
- Abscopal Stimulation of the Thymus of Rats by Exposure of the Head to X-rays (Mrs. D. Maor and Dr. P. Alexander), 40
- Absence of Growth Effects of Thalidomide on Higher Plants (E. V. Parups and I. Hoffman), 1241
- Absorption and Refractive Index Measurements at a Wave-length of 0.34  $\mu$ m. (Dr. H. A. Gebbie, N. W. B. Stone, Dr. F. D. Findlay and E. C. Pyatt), 377
- Abundance Analysis of a Supergiant in the Large Magellanic Cloud (Dr. A. Przybylski), 163
- Accuracy of Sea Gravity Surveys : Comparisons of Shipboard and Submarine Gravity Values (Dr. B. D. Loncarevic), 32
- Acenaphthene Series, Migration of t-Butyl, and Disproportionation : Mechanisms of Reactions in the (Dr. A. T. Peters), 170
- Acetate Assimilation and its Significance for Quantum Measurements in Photophosphorylation : Quantum Requirement for (Dr. W. Wiessner), 56
- Acetylcholine as a Growth Factor in Early Larval Development of the Silkworm (Dr. K. Hayashi, M. Kato and Y. Hamamura), 620
- Acetylcholine in Mixtures of Substances with Acetylcholine-like Activity : Inability of Parallel Bio-assay to recognize (Prof. E. A. Hosein and T. Y. Koh), 1119
- Acetylcholine Output : Mesencephalic Reticular Activating System and Cortical (Prof. T. Kanai and Prof. J. C. Szerb), 80
- Acetylcholinesterase Activity at Muscle-tendon Junctions : Development of (Dr. J. Zelená), 295
- Acid Deoxyribonuclease Activity in Peripheral Leucocytes of Swiss Mice (Dr. O. S. Atwal, F. L. Frye and Prof. J. B. Enright), 185
- Acid Mucopolysaccharides of the Rabbit's Dermis following Skin Treatment with Irritating Substances : Metabolism of (Dr. G. Prodi and Dr. R. Laschi), 184
- Acid Secretion and Electrogenesis in Isolated Rat Stomach (Dr. J. T. Cummins and Dr. B. E. Vaughan), 1329
- Acorn Lectures, Vol. 2, 1267
- Acridine Orange : Demonstration of Neutral Polysaccharides with Fluorescence Microscopy using (Dr. G. P. Dutta), 712
- Staining of Bacteriophage Nucleic Acids with (D. E. Bradley), 1230
- Acrylamide Gel : Zone Electrophoresis of Human Parotid Saliva in (T. S. Meyer and Dr. B. L. Lambert), 1215
- Actinomycin D Inhibition of the Adaptation of Renal Glutamine-deaminating Enzymes in the Rat (Dr. L. Goldstein), 1330
- Actinomycin D, and Pretreatment of the Host Cell with Ultra-violet Light : Effect on Myxovirus of Mitomycin C, (R. Rott et al.), 1187
- Actinophag (Phase A) active against a Strain of *Streptomyces* producing Novobiocin : Isolation and Characterization of an (Dr. C. Hengeller et al.), 418
- Action of Non-penetrating Heavy Metals on the Catalase Activity of Yeast Cells (Prof. J. G. Kaplan), 76
- Activated Chemisorption of Hydrogen on Copper Films (Dr. J. Pritchard), 1208
- Activation of Lysosomes by Oxygen (Dr. C. B. Sledge and J. T. Dingle), 140 ; (Dr. A. C. Allison), 140
- Activity of 6-Aminonicotinamide against Vaccinia Virus *in vitro* (F. J. Stanfield and J. D. McColl), 1033
- Activity and Mechanism of Action of 6-Methylthiopurine Ribonucleoside in Cancer Cells Resistant to 6-Mercaptopurine (Dr. L. L. Bennett, jun., Dr. R. W. Brockman, H. P. Schnebli, S. Chumley, Dr. G. J. Dixon, Prof. F. M. Schabel, jun., E. A. Dulmage, Dr. H. E. Skipper, Dr. J. A. Montgomery and H. J. Thomas), 1276
- Actomyosin by overcoming Substrate Inhibition : Evidence that Calcium activates the Contraction of (Prof. H. M. Levy and E. M. Ryan), 703
- Actomyosin to some Denaturing Agents : Influence of D<sub>2</sub>O on Resistance of Plant and Animal Cells, Cellular Models and (V. Y. Alexandrov et al.), 286
- Acton, Prof. H. B. : The Critical Approach to Science and Philosophy, review, 841
- Adams, Dr. C. E., et al. : Enzymatic Action of Lipoglycoprotein Preparations from Sperm-acrosomes on Rabbit Ova, 498
- Adams, Dr. D. M., et al. : Compounds containing Mercury-Iron Bonds, 589
- Adams, G. E., et al. : Rate Constant for the Reaction of O<sup>-</sup> with Oxygen, 898
- Adams, Prof. J. A. S., and Lowder, W. M. (edited by) : The Natural Radiation Environment, review by Dr. H. D. Evans, 842
- Adams, Dr. P. A., and Heath, J. E. : Temperature Regulation in the Sphinx Moth during Flight, 309
- Adams, Dr. P. R., et al. : Inhibitory Effect of Progesterone on the Activity of Human Myometrial Actomyosin Adenosinetriphosphatase, 701
- Adams, Dr. R. D., et al. : Volcanic Eruption on Raoul Island, November 1964, 743
- Adams, Prof. R. N., et al. : Homogeneous Electron Exchange Reactions of Aromatic Molecules, 382
- Adams, W. A., et al. : Effect of Cobalt on the Non-nodulated Legume, 307
- Adenosine Analogues as Inhibitors of Blood-platelet Aggregation and as Vaso-dilators in Man : Comparative Effectiveness of (Prof. G. V. R. Born et al.), 678
- Adenosine Diphosphate : Temperature and the Aggregation of Rabbit Platelets by (Dr. J. W. Constantine), 1075
- Adenosine Diphosphate *in vivo* : Platelet Reaction to (Dr. M. D. Silver et al.), 91
- ADP-induced Human Platelet Aggregation ? Is Fibrinogen the Plasma Co-factor in (J. P. Caen), 1120
- Adenosine Diphosphate, Relationship of Appearance of, Fibrin Formation and Platelet Aggregation in the Haemostatic Plug *in vivo* (Mrs. J. Marr, Dr. J. J. Barboriak and Dr. S. A. Johnson), 259
- adenosine 3',5'-monophosphate : Effect of Prostaglandin (PGE<sub>1</sub>) on the Permeability Response of Toad Bladder to Vasopressin, Theophylline and (Dr. J. Orloff et al.), 397
- Adenosinetriphosphatase : Inhibitory Effect of Progesterone on the Activity of Human Myometrial Actomyosin (Dr. D. Kumar et al.), 701
- Adenoviruses of Rosen's Group II : DEAE-Chromatography of (H. Gelderblom et al.), 625
- Adigiytov, F. I., et al. : Pathogenicity of Rous Sarcoma Virus for Monkeys, 1123
- Adipose Tissue : *In vitro* Interference of Antidepressants with Lipolytic Action of Adrenaline on (Dr. V. Vitek et al.), 90
- Adipose Tissue *in vivo* : Circulatory and Metabolic Processes in (L. Oro et al.), 178
- Adrenal Cortex : Effect of Age and Hormonal State on the Numbers of Deoxyribonucleic Acid Synthesizing Nuclei in Rat (H. P. R. Bury and Dr. W. A. J. Crane), 301
- Adrenal Gland in *Rana temporaria* : Cyclic and Experimentally-induced Changes in the Histology of the (J. A. M. van Kemenade and Dr. W. J. van Dongen), 195
- Adrenal Medulla : Survival of Chromaffin Cells in Organ Culture of the (O. Eränkő and A. Kahri), 1229
- Adrenal Medulla Sub-cellular Fractions : Distribution of Metals and Catecholamines in Bovine (Dr. J. L. Borowitz et al.), 42
- Adrenal Medullary Hormones and Sensitization of Mice to Histamine by the Histamine-sensitizing Factor of *Bordetella pertussis* (R. K. Bergman and J. Munoz), 910
- Adrenaline on Adipose Tissue : *In vitro* Interference of Antidepressants with Lipolytic Action of (Dr. V. Vitek et al.), 90
- Adrenaline in Mice : Influence of Amino-oxidase Inhibitors on the Psychomotor Depression produced by an Intraperitoneal Injection of (Prof. E. Fischer et al.), 1225
- Adrenergic Neurone-blocking Agents on the Submaxillary Gland of the Cat : Effects of (M. J. Davey, R. F. Davies, Dr. H. Reinert and P. C. Scholfield), 673
- Adult Education in Britain, 237
- Advances in Catalysis and Related Subjects (edited by D. D. Eley, H. Pines and P. B. Weisz), Vol. 14, review by D. A. Dowden, 323
- Advances in Electronics and Electron Physics, Vol. 18 (edited by L. Marton), review by Dr. J. R. Tillman, 1251
- Advances in Insect Physiology, Vol. 2 (edited by J. W. L. Beament, J. E. Treherne and Sir Vincent Wigglesworth), review by Prof. J. W. S. Pringle, 633
- Advances in the Kinetics of Homogeneous Gas Reactions (Prof. Z. G. Szabó), review by Prof. P. G. Ashmore, 1042
- Advances in Oral Biology, Vol. 1 (edited by P. H. Staple), review by Prof. R. B. Lucas, 431
- Advances in Organic Chemistry, Vols. 3 and 4, (edited by R. A. Raphael, E. C. Taylor and H. Wynberg), review by Dr. J. Idris Jones, 118
- Advances in Radio Research, Vols. 1 and 2, (edited by J. A. Saxton), review by Prof. F. G. Smith, 6
- Advisory Council on Scientific Policy, Annual Report (Cmd. 2538), 319, 347
- Aerobacter aerogenes by Sodium Chloride : Inhibition of Growth of (P. G. D. Naylor), 420
- 'Aerolite' and 'Araldite' Bonding Media (H. B. Milner), 1167
- Aerosol : Identification of Carbonic Anhydrase in an Atmospheric (L. Balcarczyk and E. Lanzel), 797
- Aerosol in Long, Thin Conduits : Turbulent Flow Deposition of an (H. Flyger and H. C. Rosenbaum), 62
- Afferent Discharges from Laryngeal Articular Mechanoreceptors (J. A. Kirchner and B. Wyke), 86
- Aflatoxins and 'Albinism' in Plants (Dr. R. Schoental and A. F. White), 57
- Africa : Organization of Research and Training in, 1165
- Scientific Research and Training in, 1141
- African Universities and Western Tradition (Sir Eric Ashby), review by Dr. P. C. C. Evans, 731
- Agar Film Technique for assaying Lengths of Mycelium in Soil : Modifications of the (A. Thomas, D. P. Nicholas and Dr. D. Parkinson), 105
- Agar gel : Failure of Spleen Cells from Immunologically Tolerant Mice to form Antibody Plaques to Sheep Erythrocytes in (Prof. H. Friedman), 508
- Agar-gel Electrophoretic Esterase Patterns in Houseflies (the late Dr. K. Van Asperen and Miss M. E. Van Mazijk), 1291
- Agar-gel Plate Technique for Antigen Analysis : Immunosedimentation : A Bi-dimensional (Prof. F. Córdoba et al.), 565
- Agar Isolation of Mycoplasmas from Human Leukaemic Bone Marrow : Direct (Dr. L. Haylick and Prof. H. Koprowski), 713
- Agarwal, Prof. S. L., et al. : Chloroquine in Dextran Oedema, 914
- Age : Absorption and Retention of Ingested Strontium and Calcium in Beagles as a Function of (Prof. R. J. Della Rosa et al.), 197
- Age Determination in Baleen Whales (*Mystacoceti*) (A. V. Yablokov and T. V. Andreyeva), 412
- Age Determinations on Three African Carbonatites (N. J. Snelling), 491
- Age of the Caledonian Orogeny and Metamorphism in Britain (Dr. W. E. Tremlett), 1202
- Age of the Transition in the Pre-Cambrian Atmosphere (R. T. Cannon), 586
- Ageing : Elastolysis and (D. A. Hall), review by Dr. G. C. Wood, 938
- Ageing (Dr. A. Comfort), revised edition, review by Dr. D. A. Hall, 1252
- Ageing Hypophysectomized Rats : Delayed Onset of Proteinuria in (Dr. A. V. Everitt and L. K. Duvall), 1016
- Agno, Prof. M. : Does Quantum Mechanics exclude Life ?, 1306
- Agglutination of Chicken Erythrocytes : Inhibition Investigations with the Hi (Dr. S. L. Scheinberg and R. P. Reckel), 250
- Agglutinogens of *Staphylococcus aureus* : Studies of Group (Dr. J. O. Cohen), 917
- Agin, D. : Charge-transfer Complex between Procaine and Ribonucleic Acid, 805
- Agin, D., and Holtzman, D. : Effect of Trypsin on Resting Potential of Frog Muscle, 911
- Aggregation Behaviour of Embryo-chick Fibroblast Cells : Inhibitory Effect of p-Benzquinone on the (Prof. B. M. Jones), 1280
- Agren, Prof. G., and Ronquist, G. : <sup>32</sup>P-labelling of Nucleotides from a Soluble Erythrocyte-membrane Fraction devoid of Haemoglobin, 1021
- Agricultural Institute of Ireland (An Foras Taluntais), 749
- Agricultural Research Centre, West Germany, 752

- Agricultural Research : Anglo-Soviet Co-operation in, 234  
The Principles and Practice of (Dr. S. C. Salmon and Dr. A. A. Hanson), review by W. J. Ridgman, 636
- Agricultural Research Council, Annual report, 1962-63, 449
- Agriculture and Horticulture : Research on Shelter in (Dr. J. M. Caborn), 551
- Agu, Dr. B. N. C. : Observation of Radioactive Fall-out in Nigeria up to 1961, 649
- Air at an Altitude of 3,500 km. : Determination of the Density of (K. Fea), 379
- Air at High Voltages : Electrical Breakdown of (W. E. V. J. Davies et al.), 1092
- Air Separation Plants : Safety in (K. Jones and R. Green), 67
- Air Showers : Radio Pulses from Extensive Cosmic-ray (Dr. J. V. Jelley et al.), 327
- Aisenberg, Dr. A. C. : Quantitative Estimation of the Reactivity of Normal and Hodgkin's Disease Lymphocytes with Thymidine- $2^{14}\text{C}$ , 1233
- Aisenberg, Dr. A. C., and Wilkes, B. : Partial Immunological Restoration of Neonatally Thymectomized Rats with Thymus-containing Diffusion Chambers, 716
- Ajl, Prof. S. J., et al. : Reaction of Pyridine Nucleotides with 2,4-Dinitrophenylhydrazine, 502
- Al $_{2}\text{O}_3$ - $\text{SO}_3$ - $\text{H}_2\text{O}$  at Temperatures Above 100°C : New Phases in the System (N. F. Dyson and T. R. Scott), 358
- Al-Askari, Dr. S., et al. : *In vitro* Studies on Homograft Sensitivity, 916
- Alber, H. K., and Alber, W. R. : *Obituary* of Dr. A. A. Benedetti-Pichler, 1158
- Albert, Prof. Z. : Gamma-glutamyl Transpeptidase in Cancers of Different Human Organs, 407
- 'Albinism' in Plants : Aflatoxins and (Dr. R. Schoental and A. F. White), 57
- Albu, A. : appointed a member of the Medical Research Council, 236
- Albumen Protein and Behaviour in the Elder Duck : Polymorphisms in Egg (Dr. H. Milne and Dr. F. W. Robertson), 367
- Albumin at Different Temperatures : Intrinsic Viscosity Measurements of Bovine Serum (Mrs. A. Chatterjee), 386
- Albumin on Transplanted Ehrlich Ascites Tumour in Mice : Effect of Purinoyl Human Serum (Y. Sinai et al.), 192
- Alburn, Dr. H. E., et al. : Seleno-cystathionine, a Pharmacologically Active Factor in the Seeds of *Lecythis ollaria*, 1185
- Alcohol Dehydrogenase : An Effect of Ethambutol, 2,2'(Ethylene)dilimino-Di-l-Butanol, on the Structure and Activity of (E. A. Peets), 241
- Aldehydes with Phenylenediamines : Reaction of Collagen-cross-linking (Dr. R. A. Milch), 1108
- Alexander, Prod. K. J. W. : The Economics of the Developing Countries, review, 1045
- Alexander, Dr. P., et al. : Progress of Cancer Research, 124
- Alexander, Dr. P., and Maor, Mrs. D. : Abscopal Stimulation of the Thymus of Rats by Exposure of the Head to X-rays, 40
- Alexandrov, Prof. V. Y., et al. : Influence of  $\text{D}_2\text{O}$  on Resistance of Plant and Animal Cells, Cellular Models and Actomyosin to some Denaturing Agents, 286
- Alkylating Agents : Cytotoxic Activity Compared with Photometric Measurements of Selected (R. P. Sanderson et al.), 479
- Alkylation : Recovery from the 'Lethal' Effects of Cross-linking (Dr. A. Loveless et al.), 980
- All-or-none Traits and the Sensitivity of Experiments (Prof. W. A. Becker and G. E. Bearse), 110
- Allen, Prof. C. W. : *Obituary* on Mrs. C. C. L. Gregory, 342
- Allen, R. D., and Kamiya, N. (edited by) : Primitive Motile Systems in Cell Biology : Proceedings of a Symposium on the Mechanism of Cytoplasmic Streaming, Cell Movement, and the Saltatory Motion of Subcellular Particles, Princeton University, 1963, review by Prof. B. Dawes, 532
- Allergic Serum : Use of DEAE-'Sephadex' for the Fractionation of (Dr. L. Goodfriend et al.), 718
- Allinikov, S. : Phototropic Enzyme-dye Complexes, 492
- Allison, Dr. A. C. : Activation of Lysosomes by Oxygen, 140
- Allium cepa Var. 'White Lisbon' after Administration of Tritiated Thymidine : Labelled Cytoplasmic Organelles in (G. C. Budd and G. M. Mills), 524
- Allogeneic Mouse Radiation Chimaeras : Dissociation of Skin Homograft Tolerance and Donor Type Gamma Globulin Synthesis in (N. L. Warner et al.), 1077
- Alloys : Influence of Impurities on the Oxidation of Fe-26Cr (D. Caplan and M. Cohen), 690
- Alonso, Dr. P., and Pérez-Silva, Dr. J. : Giant Chromosomes in Protozoa, 313
- Altstein, Dr. A. D., et al. : Anitgenic Variability of the Strains of Rous Sarcoma Virus, 826
- Alumina on Desorption of Gases : Electrification of Porous (A. C. Montefinale et al.), 996
- Amalgam-Acid Solution Interface : Kinetics of Oxygen Reduction on the (I. Mádi), 278
- Ambe, Dr. F., et al. : Recoil Effects of Neutron Reactions in Sodium Bromate, 688
- Amberlite Ion Exchange Resins Laboratory Guide, 451
- American Association of Physics Teachers Awards, 1267
- American Institute of Aeronautics and Astronautics : Goddard Award, 346
- American Museum of Natural History, 1959 Expedition to New Guinea, 235
- American Physical Society Prize Award for 1964, 346
- American Society for the Study of Sterility, 1055
- Amines : Biogenic (edited by H. E. Himwich and W. A. Himwich), review by Dr. H. Weil-Malherbe, 1043
- Amines and Amino-acids in some Reactions of Ninhydrin : Free Radicals derived from (Dr. J. C. Orr), 1008
- DL-Amino-acid by a Stereospecific Ligand Exchange Reaction : Optical Resolution of a (Prof. K. Harada), 590
- Amino-acid Composition of Human Dermal Collagen (Dr. R. Fleischmajer and Prof. L. Fishman), 264
- Amino-acid Composition and Partial Specific Volume of Citrate Oxaloacetate Lyase (T. J. Bowen and L. J. Rogers), 1316
- Amino-acid Control of Streptomycin Action on Mammalian Cells (Prof. M. Moskowitz and N. Kelker), 476
- Amino-acid Sequence of Sperm Whale Myoglobin (Dr. A. B. Edmundson), 883
- Amino-acid Transport by Sugars : Inhibition of Intestinal (Dr. S. J. Saunders and Prof. K. J. Isselbacher), 700
- Amino-acid Transport in Isolated Rabbit Ileum : Interactions between Active Sodium Transport and Active (Dr. S. G. Schultz and Dr. R. Zalusky), 292
- Amino-acids in some Reactions of Ninhydrin : Free Radicals derived from Amines and (Dr. J. C. Orr), 1008
- Amino-acids on Hands (Dr. P. B. Hamilton), 284
- Amino-acids in Shell Structures of *Gyralius trochiformis* Stahl, from the Tertiary of Steinheim, Germany : Comparative Studies of (Dr. E. T. Degens and S. Love), 876
- $\beta$ -Amino Isobutyric Acid in the Mouse : Elimination after Intravenous Administration of Deoxyribonucleic Acid : Urinary (Prof. R. Truhart et al.), 806
- 6-Aminonicotinamide against Vaccinia Virus *in vitro* : Activity of (F. J. Stanfield and J. D. McColl), 1033
- 6-Aminonicotinamide on Chick Embryo Tissue Cultures infected with Vaccinia and other Viruses : Further Observations on the Effect of (S. H. S. Lee), 1242
- Amino-oxidase Inhibitors on the Psychomotor Depression produced by an Intraperitoneal Injection of Adrenaline in Mice : Influence of (Prof. E. Fischer, J. Orlando and R. L. Ludmer), 1225
- Ammonium Requirement for Embryogenesis *in vitro* (W. Halperin and Prof. D. F. Wetherell), 519
- AMOCO Group : North Sea Licences for the Gas Council, 961
- Amperometric Procedure for the Rapid Determination of Reduced Glutathione in Red Cells : An Improved (Dr. A. J. Grimes), 94
- Taka-Amylase A : Substrate Effect on Heat Inactivation of (G. Tomita and S. S. Kim), 46
- Amylase Activity in Serum Proteins : Distribution Pattern of (Dr. M. A. Rahman), 973
- Amyloid Stain : Non-specificity of Thioflavine-T as an (B. McKinney and C. Grubb), 1023
- An Expanding Earth? (Dr. K. M. Greer), 539
- An Foras Taluntais, Director appointed, 749
- Anabaena flos-aquae A-37 : Pure Culture of (Prof. R. G. Tischer), 419
- Anaemia : Oral Treatment of Pernicious (Dr. I. Palva and Dr. O. Heinivaara), 393; (Dr. F. S. Mooney and Dr. J. G. Heathcote), 393
- Anaesthesia and Receptive Fields (A. D. J. Robertson), 80
- Anaesthetic Agent in Cold-blooded Vertebrates : Propoxate (R7464) : A New Potent (D. Thienpont and C. J. E. Niemegeers), 1018
- Anaesthetics : Significance of Work Shifts in Experimental *Schistosomiasis mansoni* with Emphasis on the Action of (M. T. Khayyal), 1331
- Anaesthetics on the Duration of Embolization of Platelet Thrombi formed in Injured Blood Vessels : Effect of (Prof. G. V. R. Born and Dr. R. B. Philip), 398
- Analgesic Effects of Morphine and Codeine in Rats : Interaction of the (T. Jóhannesson and Prof. L. A. Woods), 811
- Analysis of the Absorption Spectrum of Solutions of Uranyl Compounds (Dr. S. De Jaegere and T. Govers), 900
- Analysis of Ancient Metals (Prof. E. R. Caley), review by Dr. E. T. Hall, 1146
- Analysis of Foveal Densitometry (Prof. H. Ripps and Dr. R. A. Weale), 52
- 'Analytical Chemistry and Applied Spectroscopy', conference, 657
- Analytical Methods for Pesticides, Plant Growth Regulators, and Food Additives, Vol. 2, (edited by G. Zweig), review by Dr. M. Pyke, 431
- Ananthakrishnan, Dr. R., and Thiruvengadathan, A. : Relation between Wind and Pressure at Low Latitudes, 166
- Anaphylactic Death in the Mouse : Mechanism of (Dr. J. Munoz and Dr. R. K. Bergman), 199
- Anaphylactic Shock in Bursectomized Chickens : Reduction of (K. Sato and Prof. B. Glick), 612
- Anatomical Adaptations for Olfaction in the Snow Petrel (B. G. Bang), 513
- Anatomical Lectures of William Harvey (edited by Dr. G. Whitteridge), review by Sir Russell Brock, 838
- Ancient Metals : Analysis of (Prof. E. R. Caley), review by Dr. E. T. Hall, 1146
- Anderson, Dr. A. C., et al. : Absorption and Retention of Ingested Strontium and Calcium in Beagles as a Function of Age, 197
- Anderson, B., et al. : Observations of the Quasi-stellar and Other Radio Sources with an Interferometer of Resolving Power 0.4 sec of Arc, 375
- Anderson, N. S., et al. : Evidence for a Common Structural Pattern in the Polysaccharide Sulphates of the Rhodophyceae, 1060
- Andersson, S. A. : Intracellular Postsynaptic Potentials in the Somatosensory Cortex of the Cat, 297
- Andrews, D. P. : Perception of Contours in the Central Fovea, 1218
- Andrews, R. S., and Pridham, Dr. J. B. : Structure of a Dopa Glucoside from *Vicia faba*, 1213
- Andreyeva, T. V., and Yablokov, A. V. : Age Determination in Baleen Whales (Mystacoceti), 412
- Anelastic Solids : Stress Waves in (edited by H. Kolsky and W. Prager), review by Prof. G. J. Kynch, 942
- Anethum graveolens L. : *In vitro* Production of Neomorphs in (Prof. B. M. Johri and C. B. Sehgal), 1337
- Angiospermous Hemiparasites (R. N. Govier and Prof. J. L. Harper), 722
- Angiosperms : Recent Advances in the Embryology of (edited by P. Maheshwari), review by Dr. P. R. Bell, 1044
- Angular Sizes of the X-ray Sources in Scorpio and Sagittarius (M. Oda, G. Clark, G. Garmire, M. Wade, Prof. R. Giacconi, Dr. H. Gursky and J. Waters), 554
- Animal Ancestors (S. Cole), review by Mrs. S. C. Coryndon, 326
- Animal Cells, Cellular Models and Actomyosin to some Denaturing Agents : Influence of  $\text{D}_2\text{O}$  on Resistance of Plant and (V. Y. Alexandrov et al.), 286
- Animal Virus Research Institute, Pirbright, Report 1961-63, (Prof. M. G. P. Stoker), 453
- Animals : Phytate Metabolism in (Dr. N. K. Jenkins), 89
- Animals and Plants of the Cenozoic Era (Dr. R. Pearson), review by G. F. Mitchell, 218
- Anion in  $\text{Cs}_2\text{ReBr}_{11}$  : ( $\text{ReBr}_6$ ) $^{3-}$  (M. Elder and Dr. B. R. Penfold), 276
- Annals of the New York Academy of Sciences, 115, 1162
- Annual Cycle in the Size of the Gut of the Purple Sea Urchin, *Strongylocentrotus purpuratus* (Stimpson) (Dr. J. M. Lawrence, A. L. Lawrence and N. D. Holland), 1238
- Annual Growth Rate, 547
- Antagonism between  $\text{Na}^+$  and  $\text{Ca}^{2+}$  at the Neuromuscular Junction (J. S. Kelly), 296
- Antarctic Base : The New British, 349
- Antechinus : Locomotion in the Australian Marsupial (Dr. W. D. L. Ride), 199
- Anthocyanin Synthesis in Apple Skin : Photoreceptive Pigments for (Dr. R. J. Downs et al.), 909
- Meta-Anthracite : Electron Microscopy of Graphitic Crystallites in (J. T. McCartney and Dr. S. Ergun), 962
- Anthropology : Explorations in Cultural (edited by W. H. Goodenough), review by Prof. R. Firth, 732
- Social (Prof. P. Bohannon), review by Prof. R. Firth, 732
- Antibacterial Activity of a Variety of Viruses (B. Shore and Dr. S. S. Schneiersen), 827
- Antibacterial Effect of Natural Coumarin Ostruthine by Vitamins K : Neutralization of the (V. Dadák), 709
- Antibiotics on Chromosomes of Cultured Human Leucocytes : Effects of (Dr. R. Neu, Dr. M. J. Aspillaga and Prof. L. I. Gardner), 171
- Antibodies and Delayed Hypersensitivity : Specificity of Guinea-pig (Dr. F. Borek and Dr. A. M. Silverstein), 299
- Antibody Formation and the Coding Problem (Prof. F. Haurowitz), 847
- Antibody in the Goat : Relation between Serum and Colostrum (Dr. F. A. Green), 803
- Antibody Plaques to Sheep Erythrocytes in Agar Gel : Failure of Spleen Cells from Immunologically Tolerant Mice to form (Prof. H. Friedman), 508
- Antibody-producing Cells : Electron Micrography of (Dr. A. E. Bussard and Dr. J. L. Binet), 675
- Antibody Staining of Tissue Cultures : Simplified Method for Fluorescent (Prof. F. Deinhardt and R. E. Dedmon), 1122
- Antibody Technique : Localization of Erythropoietin in Glomeruli of Sheep Kidney by Fluorescent (J. W. Fisher et al.), 611

- Anticholinesterase Activity of Tetrahydroaminacrine and Succinyl Choline Hydrolysis (A. K. S. Ho and S. E. Freeman), 1118
- Antidepressants with Lipolytic Action of Adrenaline on Adipose Tissue: *In vitro* Interference (Dr. V. Vitek et al.), 90
- Antifouling and Anti-corrosion System (B. Wisely), (203, 1132), corrigendum, 960
- Antigen Complement-fixation Tests in Topoplasmiosis with Purified (Dr. J. D. Fulton and Prof. F. Fulton), 776
- Role of Non-specific Protein in the Sensitization of Red Blood Cells by (Prof. M. Richter and J. Cohen), 610
- Antigen Analysis: Immunosedimentation: A Bi-Dimensional Agar-gel Plate Technique for (Prof. F. Cordoba et al.), 565
- Antigen-Antibody Combination: Demonstration of the Exposure of New Antigenic Determinants Following (C. S. Henney et al.), 1079
- Antigen-Antibody Complex: Molecular Mechanism of Formation of an (Dr. A. Feinstein and Dr. A. J. Rowe), 147
- Antigen-Antibody Precipitin Reactions: A Rapid Technique for detecting Multiple (F. A. Zydeck et al.), 189
- Antigen-containing Ribonucleic Acid Preparations from Macrophages: Immunogenicity of (Dr. B. A. Askonas and Dr. J. M. Rhodes), 470
- Antigen MuB and its Relation to Haemolytic Complement: Inheritance and Properties of the (Prof. B. Cinader et al.), 97
- Antigenic Components in Human Pituitary Follicle-stimulating Hormone Preparations of Various Purities (A. Wolf), 504
- Antigenic Determinants Following Antigen-Antibody Combination: Demonstration of the Exposure of New (C. S. Henney et al.), 1079
- Antigenic Dissimilarity between Mother and Foetus on Placental Size in Mice: Effects of (D. A. James), 613
- Antigenic Uniqueness of Bence Jones Proteins (Prof. R. L. Nachman and Dr. R. L. Engle, jun.), 291
- Antigenic Variability of the Strains of Rous Sarcoma Virus (Prof. A. T. Kravchenko, Dr. A. D. Alstein, Dr. E. S. Voronin and Dr. R. M. Radsichovskaya), 826
- Antigens: Immunoelectrophoretic Analysis of *Ascaris suum* (J. Tormo and A. Chordi), 983
- Gm Antigens, Efficiency of Searching, for Identification of Blood-stains in Forensic Medicine (Dr. J. Ducos, J. Ruffe and M. Varsi), 1332
- Antigens 'I' and 'II' in Health and Disease: Reciprocal Relationship of (Dr. W. J. Jenkins, W. L. Marsh and E. R. Gold), 813
- Antimicrobial Agents and Chemotherapy (Dr. D. Perlman), 660
- Antimutagenic Effect against Colchicine of Kinetin in Black Currant Seedlings (J. M. Zatyko, I. Simon and F. Sagi), 422
- Antiproton Intensities: Upper Limits on Galactic Cosmic Ray (Prof. S. N. Milford and S. Rosen), 582
- Antisera: Preparation of Fluorescent Polyvalent *Salmonella* (D. L. Georgala and M. Boothroyd), 521
- Antitumour Activity of N-( $\beta,\beta$ -dichlorodiethylaminomethyl)-tetracycline, 'Tetracycline-mustard' (M. A. Kaplan, Dr. W. T. Bradner, F. H. Buckwalter and Dr. M. H. Pindell), 399
- Antitussive Activity of Medazomamide (G. Maffii, B. Silvestrini and S. Banfi), 914
- Anti-viral Activity of Two Guanidine Derivatives *in vitro* (B. Loddio and G. L. Gessa), 401
- Apes, New Fossil, from Egypt and the Initial Differentiation of Hominoidea (Prof. E. L. Simons), 135
- Aphid: Detection of Lipids in the Honeydew of an (Prof. F. E. Strong), 1242
- Aphid Salivation and Ingestion: Identification of Electrically Recorded Curve Patterns associated with (Dr. D. L. McLean and M. G. Kinsey), 1130
- Aphis pomi DeGeer, a Probable Vector: Persistence of *Erwinia amylovora* in the Apple Aphid (S. B. Plurad et al.), 206
- Apple Aphid (*Aphis pomi* DeGeer), a Probable Vector: Persistence of *Erwinia amylovora* in the (S. B. Plurad et al.), 206

## CONTENTS

	<i>Page</i>
TELEVISION AS A SOCIAL INFLUENCE . . . . .	1
QUANTITY AND QUALITY IN SCIENCE AND TECHNOLOGY . . . . .	2
INHERITANCE, CHROMOSOMAL AND OTHERWISE. By Prof. G. Pontecorvo, F.R.S. . . . .	4
A FARRAGO OF BIOLOGY. By Dr. J. S. Wilkie . . . . .	5
TECHNOLOGY OF COMMUNICATION . . . . .	5
RECENT RADIO RESEARCH. By Prof. F. G. Smith . . . . .	6
A MODERN TREATISE ON CHEMICAL KINETICS. By Dr. D. Husain . . . . .	6
RESEARCH IN MOTIVATION. By Dr. B. Semeonoff . . . . .	7
SCIENTIFIC AND TECHNICAL LIBRARIES. By L. Wilson . . . . .	8
THE SCIENCE OF SCIENCE FOUNDATION. By Maurice Goldsmith . . . . .	10
THE SCOTTISH RESEARCH REACTOR CENTRE. By Dr. Henry W. Wilson . . . . .	10
INTERNATIONAL CONFERENCE ON EARTH SCIENCES. By Prof. H. G. Houghton . . . . .	15
ORGANIC GEOCHEMISTRY. By Dr. G. D. Hobson . . . . .	16
RELATIONSHIP OF BIOLOGICAL REGULATORY MECHANISMS TO LEARNING AND MEMORY. By Dr. Samuel H. Barondes . . . . .	18
OBITUARIES:	
PROF. W. H. PEARSALL, F.R.S. By Dr. J. W. G. Lund, F.R.S. . . . .	21
PROF. VINCENT NECHVÍLE. By Prof. Zdeněk Kopál . . . . .	21
PROF. W. KLÜPFEL. By Miss M. Casimir . . . . .	22
NEWS AND VIEWS . . . . .	22
EDUCATION FOR BUSINESS AND MANAGEMENT . . . . .	27
SCIENTIFIC AND INDUSTRIAL RESEARCH IN NEW ZEALAND . . . . .	27
SCIENTIFIC POLICY IN BELGIUM . . . . .	28
REGIONAL ADMINISTRATION IN FRANCE . . . . .	29
THE BUILDING RESEARCH STATION . . . . .	29
STRUCTURE AND INTEGRATIVE FUNCTIONS OF NERVOUS SYSTEMS. By Dr. G. M. Hughes . . . . .	30
ACCURACY OF SEA GRAVITY SURVEYS: COMPARISONS OF SHIPBOARD AND SUBMARINE GRAVITY VALUES. By Dr. B. D. Lončarević . . . . .	32
GEOCHEMICAL APPLICATION OF SPARK SOURCE MASS SPECTROGRAPHY. By Prof. S. R. Taylor . . . . .	34
SOME MEASUREMENTS OF THE TENSILE STRENGTH OF DRY POWDERS OF IRREGULAR PARTICLE SHAPE. By B. B. Morgan . . . . .	36
INHALATION AND RETENTION OF FALL-OUT ZIRCONIUM-95 BY HUMAN BEINGS. By J. Rundo and D. Newton . . . . .	37
ABSCOPAL STIMULATION OF THE THYMUS OF RATS BY EXPOSURE OF THE HEAD TO X-RAYS. By Mrs. Dalia Maor and Dr. Peter Alexander . . . . .	40
DISTRIBUTION OF METALS AND CATECHOLAMINES IN BOVINE ADRENAL MEDULLA SUB-CELLULAR FRACTIONS. By Dr. J. L. Borowitz, K. Fuwa and Dr. N. Weiner . . . . .	42

# UNICAM SP.800

spectrophotometer for routine  
U.V. analysis and complete  
**automation**

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible Spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as *the* outstanding U.V. spectrophotometer. Now, in addition, Unicam offer a set of automation accessories which provide facilities for:

**AUTOMATIC** interchange of up to 4 sample and 4 reference cells

**AUTOMATIC** re-cycling over any preselected wavelength range

**AUTOMATIC** recordings at predetermined time intervals.

*Please send for descriptive brochure*

*Save operator time, increase speed and efficiency with Unicam automation for:*

**ENZYME REACTION RATES**  
**LIQUID COLUMN CHROMATOGRAPHY**  
**ALL ROUTINE ULTRAVIOLET AND VISIBLE SPECTROSCOPY**

# AGAROSE

A neutral galactose polymer obtained from Agar by a unique method using reagents having no toxicity.

- \* Negligible electroendosmotic properties.
- \* High gel strength.
- \* Non-toxic.
- \* Minimum adsorption properties.

This product and many ENZYMES and RELATED BIOCHEMICALS of the highest possible integrity are produced entirely in our own laboratories.

Moneyrow Green, Holyport,  
Maidenhead, Berks., England.

## Synthetic Polyribonucleotides

Prepared by polymerization of nucleotides with polynucleotide phosphorylase from *Micrococcus lysodeikticus*.

These polynucleotides are of high molecular weight, suitable for both physical-chemical and biochemical studies.

In stock for immediate shipment are salts of:

Polyadenylic acid  
Polyinosinic acid  
Polyuridylic acid  
Polycytidylic acid

Copolymers are custom synthesized with 2 to 4 different bases in any given ratio of substrates.

Custom synthesis of  $C^{14}$  and  $H^3$  labelled homopolymers and copolymers can also be accomplished.

For information and prices write to:

DEPT. A,

CHEMICAL COMPANY

Division of Miles Laboratories, Inc.  
ELKHART, INDIANA.

**PRECISION INSTRUMENTS**

### NEW FEATURES—

This equipment now incorporates automatic Verdet Dispersion Correction and range change switching, water jacketed sample chamber and nitrogen purging of the optical deck.

For full details and specification, price and delivery, write to Dept. N.

## The POLARMATIC 62 Automatic Spectropolarimeter

RANGE—181 to 600 millimicrons.

ROTATION—Up to 1.4 degrees at 200 millimicrons positive or negative.

SAMPLE TUBES—5, 10 and 20 mm standard. Water jacketed types available.

RECORDER—Flat bed plotter.

RECORDING TIME—200 to 600 millimicrons in 20 minutes.

Manufactured under licence. Patent No. 918078

The electronic unit for this instrument is manufactured by Messrs. Bendix Electronics Ltd., of Nottingham

## TELEVISION AS A SOCIAL INFLUENCE

THE Television Research Committee was appointed by the Home Secretary in July 1963, to initiate and co-ordinate research into the part which television plays, or could play, as a medium of communication and in fostering attitudes. The Committee was to investigate particularly the ways in which young people's moral concepts and attitudes develop, and the processes of perception through which they are influenced by television, in relation to other media of communication. It was also instructed to administer any funds which may be made available for such research, to select and clarify any relevant issues which might prove amenable to scientific enquiry, and to commission and co-ordinate the appropriate research projects. Research of this type is necessarily long-term and is a comparatively new development, and there are few experienced practitioners in Britain.

It will, accordingly, be some years before results of any new research projects are ready for publication, but in the meantime working papers aimed at assisting the Committee to clarify its own thinking will be published from time to time, which it is hoped will also encourage public discussion on the influence of television. The first of these, a survey by Mr. J. D. Halloran, the Secretary of the Committee, breaks no new ground but presents an informed summary of the effects of mass communication, particularly television, as they have appeared to the leading research workers in this field\*. It is limited essentially to source material and deliberately excludes studies on the use of television in formal education, the effects of advertising, or the use of television in propaganda and in psychological warfare. Mr. Halloran's main aims are threefold. First, to indicate the kind of knowledge about the effect of television on children which is empirical, verifiable, and which has been gathered and analysed systematically, and which may on occasion permit a generalization to be made. Secondly, to assist in mapping the problem areas. Thirdly, to provide an introduction to some of the theoretical frameworks in use and direct attention to some of the difficulties involved in the work. Besides seeing what generalizations, if any, can be made, he also endeavours to indicate some of the gaps in the research material, some of the areas not covered, and some questions which might be posed. Roughly half the booklet comprises appendixes dealing with the wider debate on mass media and mass culture, describing the work of the Committee for Research on Television and Children of the United States Department of Health, Education and Welfare, including the areas and topics suggested for research, and outlining the techniques and strategies for research into television and human behaviour proposed by the Television Bureau of Advertising in the United States.

These appendixes will give the general reader, as well as the specialist, some idea of the variety of approach which is being adopted, but the review itself is of some interest as a corrective of many loose assertions at present

made about the influence of television. It reminds us, for example, that the study by Dr. Trenaman and his colleagues of the Television Research Unit at the University of Leeds did not show that television had any major effect on the political life of the people during a three-week election campaign. We have, however, still to consider the impact over the years, and such evidence as is available suggests that influence is likely to be at its maximum when we are not aware of being 'got at' and when the context is one of which we generally approve.

Nevertheless, while the effects of communications can be many and diverse, operating at different levels and in different strengths, even when allowance is made for the part played by various mediating factors and the imperfection of the evidence, it would be wrong to assume that these effects are wholly good. All the evidence so far provided by detailed researches suggests that values are acquired, that a view of life is picked up by children watching television, and there are good theoretical grounds, largely supported by experimental and clinical evidence, for supposing that moral standards could be affected by television. Nor can the finding that children learn to like the programmes available to them, which ordinarily they would not select, be regarded without concern by those who consider that many programmes leave much to be desired.

The evidence seems fairly clear that television does not stimulate interest or broaden horizons to any greater degree than would happen in its absence. Another conclusion that deserves noting is that the viewer is more selective the older he is and the higher his cultural and educational level, and even when the positive correlation between parental and child viewing is discounted it still appears that the abler the child, the less he or she views. Several studies show that the heavy use of escapist material is associated with tendencies to anxiety, social maladjustment and frustration. However, while in consequence we can accept that this form of media content does not appear to be a prime cause of any particular way of life, Mr. Halloran reminds us that it does serve the psychological needs and reinforce the ways of life already characteristic of its viewers—the results of which are not always socially desirable or beneficial.

So far as passivity and dependence are concerned, there appears to be no evidence that television makes children passive and there is little to make us believe that violent programmes on television reduce the likelihood of violence in real life. Very little delinquency can be traced directly to the medium, but there are a number of situations in which violence might be encouraged and, although it would seem evident that heavy exposure to television is not a sufficient or crucial cause of delinquency, some work suggests that criminals are heavy users. On the whole the weight of evidence is behind the conclusion that the heavy dosage of violence in the mass media, while not a major determinant of crime or delinquency, heightens the probability that someone in the audience will act aggressively in a later situation. Here Mr. Halloran emphasizes the need for more research, and research which is not narrowly oriented. The role of mass media in

\* *The Effects of Mass Communication with Special Reference to Television: a Survey.* By J. D. Halloran. (Television Research Committee—Working Paper, No. 1.) Pp. 83. (Leicester: The University Press, 1964.) 7s. 6d. net.

this process of delinquency is undoubtedly important but it is only one aspect of the total situation.

Mr. Halloran stresses the importance of viewing the mass media of communication as functioning within the larger sociological perspective of culture, social structure and organization, and social groups. The socialization process is continuous, and is located in people and institutions, and it can be both deliberate and inadvertent. Neither its contents nor its methods are immune to the influence of mass communication, and while this represents only one aspect of the process it would be very surprising if it did not play some part in shaping our attitudes towards life, towards ourselves and towards others.

At present, conclusive evidence about the effects of mass communication is inadequate. We need to know much more about its content and the patterns of consumption and, Mr. Halloran adds, about the effect of acquiring social norms impersonally through the mass media as distinct from acquiring them through the primary groups. We need to know whether, or to what extent, the quality of the norms is changed in this process of transmission by the mass agencies; what degree of standardization is developing and what is the overall influence on the mechanisms of social control. Clearly, as he says, there are here many tasks for the research worker.

In the latter part of his survey Dr. Halloran is concerned to indicate some of the most promising lines for investigation, some at least of which are important in other connexions. He refers, for example, to the need to integrate research on mass communication into general research on child development. Communication, he reiterates, is not a one-way process, and there are consequences for group structures which should lead to the study of the larger social structure which transcends both the individual and the group. So far as research into mass communication is concerned, he suggests that it would be useful if

attempts could be made to compare the influence on message reception exerted by the primary groups on one hand, and by the larger social structure on the other, and to extend these attempts to cover different societies, sub-cultures and periods. Nor should it be forgotten that the communicator is also located within the structure of social relations and that his operations are influenced by that structural context.

Mr. Halloran thus presents the study of television not only as part of the study of mass communication but also as an integral part of the social system. It is in accord with this that, in the competition fostered in 1960-61 by the Television Bureau of Advertising in the United States, in which the awards were given for research strategies or plans, the highest award went to a programme of research into the television viewing, the norm-violating practices and the perspectives of adolescents, while the second award went to one on the application of scientific television methods to the analysis of perceptual feed-back in behaviour. While the gaps in our knowledge stressed in this first paper from the Television Research Committee fully justify the placing of generous resources at the disposal of the Committee, it is equally clear that such research should be carefully co-ordinated with social research in general. Whether in fact the Television Research Committee is appropriately placed under the Home Secretary is a matter for consideration. It would certainly appear difficult to justify a responsibility to any other Ministry than that responsible for social research in general, and, in view of the educational implications, the interrelations with educational research may call for reconsideration. Nevertheless, on the evidence of this paper alone the new Postmaster-General will be ill-advised to commit the Government too far in further extension of wave-lengths to independent television in advance of the findings of current and projected research of the type outlined in this paper.

## QUANTITY AND QUALITY IN SCIENCE AND TECHNOLOGY

IN a maiden speech on November 6 during the debate in the House of Commons on the Address to the Throne, Mr. N. Atkinson referred to the shortage of engineers and to Britain's reluctance to recognize that, in promoting technological change, engineers came first, technologists second and scientists third. Unless we could persuade more of our ablest young people to take up a career in engineering we would not have the supply of engineers needed to execute such a programme as that contemplated in the Queen's speech. This plea is also found in the Presidential address, "The Shape of Things to Come: a Challenge to Engineers", which Vice-Admiral Sir Frank Mason delivered to the Institution of Mechanical Engineers on October 28, in which he analysed at greater length the trends in secondary schools elucidated in 1962 by the Education Department of the University of Oxford in a report, *Technology and the Sixth Form Boy* (*Nature*, 199, 958; 200, 219; 1963).

Prof. I. D. Rattee has also expressed concern at those tendencies in a recent inaugural lecture, but from a different point of view (*Nature*, 204, 1017; 1964). Sir Frank Mason was concerned with the fact that the schoolboy, his masters and his parents do not think that

engineering is a worth-while occupation. In consequence, not only are we producing twice as many scientists as engineers instead of the reverse proportion which we need, but also the quality of entrants to engineering falls short of that of science students and of what is required. Admiral Mason makes some trenchant but justified comments on the situation. "Secondary Schools are ceasing to be places of education", and while he sees no hope of a rapid change, he recognizes that it is within the power of the universities, the entrance requirements of which have been an important factor, to rescue us from this ominous situation. Apart from this, it will be largely a matter of education, in which the engineer and the scientist can play an important part, if they make full use of their personal contacts.

Here Sir Frank touches one of the dominant notes of his address—professional responsibility. Only one passage in his address was concerned with the shortage of engineering students, but the note of professional responsibility struck in that passage recurs elsewhere. This is notable in his remarks on the dangers arising from university expansion, on the complementary roles of the engineer and the scientist and on the way in which the

engineering profession is meeting the challenge of to-day. Like Prof. Rattee, Sir Frank Mason is particularly anxious about the dangers of lowering standards in the unprecedented expansion of universities, particularly through the absence of sufficient teachers of the necessary calibre. He advocates not simply a critical appraisal of curricula or of teaching methods but of the methods of selection, and pointedly emphasizes the necessity of assessing the candidate's potential contribution to society. He regards with something more than disfavour the likelihood that possession of a degree will become an essential passport to every kind of job with any prospects—it would effect a disservice to both society and individual.

The warning is one we disregard at our peril. It is supported by Sir Gordon Cox's equally forthright insistence that a major problem of education is how to diminish the number of arrogant students who think that the world owes them a living beyond their real merits. To accelerate university expansion while retaining flexibility, and sufficient respect for individuals, and to pursue the quest for equality to the extent of denying opportunity to the gifted and embracing instead the mediocre and second-rate is the negation of responsibility and ultimately must be fatal to our economic development. Again, Sir Frank has the courage to question whether we are pitching our requirements for mathematics so high that we are losing many who would make good engineers; he gives a timely reminder of the importance and value of the sandwich system both to the universities and colleges of technology and to industry. He hopes that this problem will receive attention from the Industrial Training Boards and that care will be taken to prevent technical education in general from becoming too academic and theoretical.

Apart from this note of responsibility, Sir Frank's address derives much of its value from its balance and sweep. He recognizes the importance of the technicians, and while he has high hopes of the Council of Engineering Institutions he reminds the Council of its responsibility towards the technician. His suggestion here could well help the Council to overcome some of the difficulties into which it has run through the proliferation of organizations, and the problem of distinguishing between a professional and a lower qualification—a point emphasized by Mr. H. G. Conway in his presidential address to Section G of the British Association for the Advancement of Science at Southampton (*Nature*, 203, 951; 1964). The differentiation between technologist and technician is not always easy; there is a clear account of the distinctions made, and the balance maintained in the Royal Navy is apposite. Certainly, unless more attention is directed to this problem by industry and by the professional institutions there is real danger, as Sir Frank remarks, that in a few years we shall find that we have graduates doing work which really should be done by technicians: this situation would arise simply because we would have trained too many engineers and technologists and not enough technicians.

That is another aspect of the expansion of higher education which calls for much more attention than it has yet received. Elsewhere in his address Sir Frank Mason refers to the complementary roles of the engineer and the scientist, but from a different point of view from that of Prof. Rattee. Both, however, recognize the importance of research and particularly of securing the application of the results of research. Above all, however, Sir Frank recognizes the extent to which team-work is involved

and the necessity of training engineers who are not only professionally competent but are also capable of co-operating harmoniously and effectively with the accountant, the chemist, the metallurgist, the physicist, etc. He does not regard engineering as incapable of providing men with a broad outlook though he recognizes the need for some postgraduate study in management and welcomes the proposals to establish two new business schools.

Another interesting feature of Sir Frank Mason's address is the extent to which many of his remarks on, for example, the importance and functions of the Council of Engineering Institutions, the importance of engineering in our economy, or the relation between design and manufacture, anticipated those of Mr. R. M. Wynne-Edwards in his presidential address to the Institution of Civil Engineers the following week. The note of responsibility is sounded just as clearly in that latter address, even if Admiral Mason's final emphasis on the need for integrity as well as creative insight is much the more explicit. It is this interpretation of what is involved in responsibility and the idea of service that gives distinctiveness to the whole address. Sir Frank does not hesitate to affirm either his belief that man is a trinity or to point out where he believes man can renew his spiritual strength.

At this point Sir Frank's address links with the challenging address which Sir Gordon Cox delivered to the School of Pharmacy on October 14. Sir Gordon was discussing personal responsibility and technocracy and expressed some thoughts on the preparation of scientists for their responsibilities in a science-dependent society. Speaking in the context of the doubling every four years since 1945 of Government expenditure on civil science—an increase from about £7 million to about £170 million a year—and questioning whether young scientists appreciated the significance of these figures, as already noted, he felt there were too many who thought the world owed them a living beyond their deserts. Another major problem of education was how to diminish the number of those who lacked the faith to make full use of the talents they possessed. He believed that success in either direction would be attained rather through personal influence than through formal education.

This note of professional responsibility towards younger colleagues is the keynote of Sir Gordon's address and supplies its wider interest. With it he links the personal responsibility of every scientist to use his interest in spreading a real understanding of science among the population at large. Such a general understanding Sir Gordon sees as an essential condition if science and the scientist are to enjoy public confidence and support and the freedom which is essential to scientific advance and ultimately to technological advance as well. It is at this point that he emphasizes the value of the sciences, properly taught, as an educational medium, just as he stresses the need for the general public to understand the limitations as well as the nature of scientific method and the distinction between scientific and political decisions.

This is perhaps particularly important for informed public discussion on the organization of science and government where changes such as those now proposed for Britain are being made. Sir Gordon Cox does not overlook the vital importance of the gifted scientist. Scientific advance, notwithstanding all the help effective large-scale organization can give, depends above all on the creative and non-conformist individual. Organization and planning must strive to provide the conditions in which these few exceptionally gifted people can flourish and use their

creative powers most fruitfully as well as to ensure that they and their most fruitful fields of work will be identified at an early stage. Apart from this, Sir Gordon does not believe that educationally we need be too concerned with this group of exceptionally gifted people. The main task is so to organize our research and educational organization as to deserve success.

This is first a matter of attending to professional competence, and in this connexion too he emphasizes the influence which senior scientists can exercise on their younger colleagues. In this same context he is forthright about the importance of a command of good English. He has no truck with slovenly and imprecise writing, that goes with slovenly and imprecise thought. He has no doubt that new ideas are more likely to come if the old ones are formulated in precise language. That is a part of the problem of communication and its importance cannot be overstressed. Until the scientist accepts unhesitatingly that a command of good English is an essential part of his technical competence he is unlikely to be effective however conscientiously he addresses himself to the task of spreading a real understanding of science in the community. Moreover, the ease with which the results of his own scientific work are likely to be fully appreciated in industry or elsewhere depends on his eloquence.

If the challenge of all these addresses is more especially to the professional associations of scientists, engineers and other technologists and to their individual members, all three addresses point to dangers in the expansion of higher education which it would be most irresponsible to disregard. Preoccupation with numbers to the neglect of quality could thwart the whole purpose of that expansion. The Robbins Report is very far from having eliminated the need for hard thinking before even the scale of university expansion is finally determined. Even from the point of view of our economic growth, quality comes first, while from the point of view of the individual, failure to match the plans for expansion of scientific and technological education with plans to ensure provision of the requisite supply of supporting technicians and craftsmen could be as wasteful and untoward as the attempt to induce into an academic career in science or technology those whose aptitudes and desires lie elsewhere. Large institutions are not the complete answer and are certainly no insurance against frustration and disgruntlement if the broad policy is unsound and lacking in vision.

## INHERITANCE, CHROMOSOMAL AND OTHERWISE

### The Mechanics of Inheritance

By Franklin W. Stahl. Pp. xiii+171. (Englewood Cliffs, New Jersey, and London: Prentice-Hall Inc., 1964.) 21s.

### Extrachromosomal Inheritance

By John L. Jinks. Pp. xiv+177. (Englewood Cliffs, New Jersey, and London: Prentice-Hall, Inc., 1964.) 21s.

### The Cytoplasm in Heredity

By D. Wilkie. Pp. vii+115. (London: Methuen and Co., Ltd., and New York: John Wiley and Son, 1964.) 16s.

THESE are three very readable publications. That by Stahl is the exciting, concise, logical and arrogant, yet slightly insecure, product which we have come to expect when molecular biologists of high calibre start

from their immediate speciality and go beyond it. This one, in addition, is full of both very witty and feeble jokes. It is a very clear presentation of the physical basis of inheritance in bacteria and bacteriophages from the angle of the molecular biologist who works with them. The discontinuity in biological organization, that is, the dividing line between 'higher' organisms and others, is taken to be the presence of a "nucleus clearly differentiated from the cytoplasm". If by this is meant the presence of a nuclear membrane, I would certainly agree with this view, even though on its basis *Chlamydomonas* and yeast become 'higher' organisms. The book is at its weakest where—as in chapter 7, "Recombination in Higher Organisms"—it deals with processes of heredity in organisms other than phages and bacteria.

The tacit thesis is that, to learn the genetics of higher organisms, one requires the sort of epic effort which produced classical genetics: why not learn the easy way by applying to higher organisms the understanding gained from bacteria and bacteriophages? Of course, the answer is that microbial genetics is by no means simpler than that of higher organisms. In the analysis of crosses in higher organisms one seldom encounters, for example, as didactically intractable a system as that of  $F^+ \times F^-$  in *E. coli* or a situation as complex as that of an ordinary cross with phage. How would Mendel have fared if he had had to analyse a cross only after an unknown number of generations?

The genetics of bacteria and bacteriophages is simple if one already knows the principles from higher organisms. It contributes decisively, not in providing more easily the principles, but in giving a chemical basis to them. All told, this book is entertaining and useful. It is also recommendable for teaching, but only to sophisticated students.

The other two books, by Jinks and Wilkie, respectively, also make useful reading and can be used for teaching at an advanced level. The rather woolly treatment is the inevitable reflexion of the state of a subject—cytoplasmic inheritance—which has not yet had its Mendel let alone its Watson and Crick. Both books, and especially Wilkie's, are humble and they spare us feeble cracks, much as we may regret the price of not having any good ones.

Wilkie's book provides an effective summary of a small number of well-chosen examples of inheritance which are not interpretable in chromosomal terms. As to interpretations, his approach is cautious: he calls in reluctantly extrachromosomal entities endowed with genetic continuity only when every other known process appears inadequate.

In Jinks's book, in which the examples are drawn from a broader field, the mood is somewhat in the reverse direction. Yet, Jinks is careful in listing, and discussing the validity of, the criteria which should be satisfied before we accept extrachromosomal genetic structures as underlying any given case of heredity not explicable in chromosomal terms.

These three books are utterly different in outlook: Stahl is sold 100 per cent to the molecular biology of the year when he wrote; Jinks is 100 per cent a classical geneticist and steers clear of anything with a biochemical flavour; Wilkie takes an intermediate stand. Nevertheless, all three use terms such as 'genetic material', 'genetic continuity' and similar, which were indispensable in classical genetics but useless now.

We have come to recognize two quite different ways in which cell constituents are made. One involves step-by-step processes, with each step catalysed by a specific enzyme and almost no qualitative latitude in what the product of each step can be. The other involves the arrangement of low molecular weight substances of a small number of kinds—say four nucleotides or twenty amino-acids—into a precise sequence out of the myriads possible. The selected sequence is determined by a pre-existing sequence. The pre-existing and the new

sequences can be made of identical materials—as in the replication of DNA; or of different materials—as in the ‘translation’ of RNA into protein. For the former case the expression available is “template mode of replication”.

Cell division, and therefore ultimately heredity, involves stepwise as well as template processes, and among the latter replicatory as well as translationary processes. What we need from now onwards is an analysis of heredity—chromosomal or otherwise—in terms of these three types of processes, at least until they are the only ones known.

G. PONTECORVO

## A FARRAGO OF BIOLOGY

### The Evolution of Biology

By M. J. Sirks and Conway Zirkle. Pp. v+376. (New York: The Ronald Press Company, 1964.) 6 dollars.

“THE title of this book”, we read in the preface, “was chosen deliberately. It was never the intention of the authors to write a detailed history of biology. The book has now become a survey of the evolution of biology from its beginnings before the dawn of history to its most recent . . . advances.”

But “detailed” is a relative notion. To cram into some 350 pages not only the history of biology, but also some account of the knowledge of living things possessed by man before he made his first essays in scientific thought, should, we might have expected, have involved a strict adherence to what is of cardinal importance and a rigid exclusion of inessentials. In fact, what we are offered is another chatty and discursive little book—yet another ‘short history of biology’ loaded with a mass of varied information and not a little misinformation.

According to the preface, part of the book has already been published in Dutch, and inadequate translation may account for some of its oddities. For example, on p. 167, Leibniz is credited with the assertion that “the monads of animals are percipient but unconscious”. It is possible that the Dutch meant “percipient but not self-conscious”.

But there is much for which only the authors can be held responsible. Thus we are told that Buffon “was a writer rather than a scientist, a journalistic propagandist rather than an original investigator”. This is a false judgment: if the authors had not the time to examine Buffon’s admittedly voluminous writings, they could have obtained responsible accounts of them. We are given, of Lamarck’s theory of evolution, the notion based on the two misleading paragraphs so often quoted from the *Philosophie Zoologique*. This notion, that the inheritance of acquired characters was central to his theory, has more than once been shown to be erroneous.

I fail to see how Weismann’s hypotheses can be said to “form a perfect prototype of the theories to which . . . genetics still subscribes”. Weismann thought that “theoretically . . . one id would suffice for ontogeny” (*The Germ-Plasm*, London, 1893, p. 63); but he supposed the germ-plasm to consist of many, even very many ids. This is as though we were to believe that every fertilized egg contained twenty or a hundred sets of chromosomes each equivalent to the haploid set. Then, again, how can anyone say that Weismann and Hugo de Vries (even if the statement refers to 1892) “did not extend their discussions to the heredity characters themselves”? (p. 295).

The account given of ‘biology’ in antiquity is in places just as unreliable as that given of the biology of the eighteenth and nineteenth centuries. We are given (p. 29) to a year the exact dates of the birth and death of Hippocrates, and are told that through him “Greek medical knowledge became a systemized whole”; and although the expression “the writings ascribed to Hippocrates”

is used, the authors consistently write as though the whole Hippocratic corpus could be attributed with great probability to a single writer with a *floruit* about 420 B.C.

We are told (p. 31) that Empedocles “conceived of a definite evolution of living things”; whereas, of course, the most we could attribute to him would be a notion of synthesis of living forms under some sort of natural selection.

A great muddle is made (p. 36) of Aristotle’s neat classification of ‘souls’; and what is the uninitiated to make of the statement, “In plants, this soul was limited to the nourishment imbibed through the roots”?

To say (p. 38) that “The antithesis between *preformation* . . . and *epigenesis* . . . had already found an expression in the works of Aristotle” is a gross anachronism, and scarcely consistent with the statement (itself scarcely justifiable) that “the germ of the antithesis . . . between preformation and epigenesis” is to be found in Harvey’s theory of generation (p. 160).

A partial explanation of the weakness of this book is to be found in its list of secondary sources, which is most inadequate.

As a work of instructive entertainment the book has considerable merits, and it was possibly not intended to be judged as a work of scholarship.

J. S. WILKIE

## TECHNOLOGY OF COMMUNICATION

### Telecommunications

Vol. 1. By J. Brown and E. V. D. Glazier. General Editor: Prof. H. M. Barlow. Pp. xiv+370. (London: Chapman and Hall, Ltd., 1964.) 45s. net.

THE publication of this book is extremely puzzling—puzzling because there is no immediate explanation why authors of such prominence and leadership in the technology of communication should have produced a volume so lacking in original contribution, either of new material or of new points of view. Moreover, it is difficult to judge to whom the book is addressed; is it for the sixth-form schoolboy thinking of entering electrical engineering, or is it for the mature student interested in specializing? Perhaps the best that can be done here is to point out some of the bad aspects of the book and then to suggest improvements for a second edition.

The first chapter is written at schoolboy level. For example, although it is stated on p. 1 that “The reader is assumed to have a knowledge of electrical circuit theory, including alternating current theory . . .” on p. 3 it is explained that, in a pair of transmission-line wires the current flows along one wire, through the load, and back again along the other wire. Again a little later on, it is said that “radio . . . is an electromagnetic wave . . .”, equation (1) reads  $C=f\lambda$ , and on p. 6 it is stated: “1 Kilocycle/second (Kc/s) =  $10^3$  c/s”, etc. The chapter continues at this level, showing pictures of such things as the simple Morse-key telegraph, a telephone circuit and other diagrams that might appear in a *What Every Boy Wants to Know Encyclopaedia*.

It would have been much better to have omitted the whole of Chapter 1 and to have started the book at p. 24. There we are at a reasonable starting level; the distinction between (so-called) continuous signals and discrete signals is noted and Fourier theory is plunged into on p. 37. This omission is made more justifiable by the fact that, in spite of the schoolboy level of Chapter 1, the reader is faced with Fourier series equations and Fourier integral transforms, in the complex conjugate notation, as the second and third equations in the book, without any explanation by way of introduction whatsoever. The appendix dealing with Fourier theory is similar.

A further saving in size and cost of this volume might have been made by exclusion of the appendixes (72 pp.). These treat, formally, Fourier theory, convolution theorem, Laplace transforms, Heaviside's expansion theorem, and Hilbert transforms and Bessel functions. These subjects are already more than adequately treated in existing text-books. The volume would benefit by this exclusion, by directing attention more forcibly to the material in it which is less readily available elsewhere—for example, descriptions of various practical systems of radar, range-finding, direction-finding, etc.

On points of detail, the "simple deduction" on p. 204 of Shannon's capacity theorem (in statistical communication theory) is quite wrong and misleading. Again, on p. 152, the Gaussian probability distribution of 'white' noise is stated without any derivation at all; yet it could well be explained in terms of simple coin-tossing, if not rigorously derived, in a few lines. On the same page the statement appears that "this (Gaussian additive noise) . . . is appropriate for all noise phenomena of interest . . .". Alas, it is not. It is used so widely for reasons of simple mathematical tractability; more cases arise where the noise of interest is impulsive, or is cross-talk, or has other awkward forms. Several other statements of bare theoretical fact are made in the book, when simple explanations and justifications could easily have been given to assist enlightenment (for example, p. 216, the Hamming code).

This review may have seemed harsh, but with limited space it has been thought more important to criticize constructively than to praise blindly.

## RECENT RADIO RESEARCH

### Advances in Radio Research

Vol. 1. Pp. x+226. Vol. 2. Pp. xi+215. Edited by J. A. Saxton. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1964.) 50s. each.

**C**OMMUNICATION by radio waves may sometimes appear magically simple, as for example when Marconi first spanned the Atlantic, or in recent satellite relays of television broadcasts. It is, however, often attended by considerable difficulties, which have become the preoccupation both of international bodies concerned with organization and of research establishments concerned with the scientific details. There have for many years been powerful stimuli from civil and military needs, and the trends of modern research in such establishments as the Radio Research Station of the Department of Scientific and Industrial Research, and the Central Propagation Research Laboratory of the National Bureau of Standards can often be traced directly back to quite urgent practical questions. The research is nevertheless basic science, and the account given in these first two volumes of a new series has correspondingly given us a new text-book of radio research.

This collection of work is concerned basically with the propagation of radio waves through the terrestrial atmosphere. The troposphere, which is the lower part of the atmosphere, can both refract and absorb, and the extent of these aberrations is described respectively by Prof. A. W. Straiton (University of Texas) and by Dr. B. R. Bean (U.S. Central Radio Propagation Laboratory). Dr. Bean goes on to show that both troubles are at least predictable, so that, for example, the apparent position of a satellite as measured by a radio telescope can be corrected for refraction from meteorological measurements made on the ground. Prof. Straiton and Dr. Bean provide solutions to practical problems which are becoming commonplace in the age of space vehicles and of microwave communication.

Even without a troposphere, the inhomogeneous and curved surface of the Earth affects seriously the propagation of long radio waves. This has proved to be a difficult

mathematical field of research, which is now expounded by Dr. J. R. Wait (U.S. Central Radio Propagation Laboratory) in an article on electromagnetic surface waves.

A radio wave which has passed these hazards is often received against a background of noisy signals generated by atmospheric disturbances. The description of this thunderstorm noise by Mr. F. Horner (Radio Research Station, Slough) covers the source, its radiation properties and its effects on radio receivers at various places. Another natural hazard, the variability of the ionosphere, is dealt with by Dr. C. M. Minnis (Radio Research Station, Slough), who describes the correlation of ionospheric behaviour with various indices of solar activity.

Finally the scope is widened by the introduction of advanced modern techniques in an article by Dr. J. W. Findlay (U.S. National Radio Astronomy Observatory) on antennae and receivers for radio astronomy. Of particular interest here is the result of surveying the surfaces of two large radio telescopes at the National Radio Astronomy Observatory, Greenbank, by air-based photogrammetry.

These articles are without exception outstanding reviews, well presented, well illustrated and with a full list of references.

As scientific attaché in the British Embassy, Washington, D.C., Dr. J. A. Saxton has clearly found himself in a position to collect together the very best work in this field on both sides of the Atlantic. International radio only exists on the basis of international co-operation, and it is not the least of Dr. Saxton's merits that he has shown us how truly international is modern radio research.

F. G. SMITH

## A MODERN TREATISE ON CHEMICAL KINETICS

### Chemical Kinetics of Gas Reactions

By V. N. Kondrat'ev. Translated from the Russian by J. M. Crabtree and S. N. Carruthers. Translation edited by N. B. Slater. Pp. xiv+812. (London and New York: Pergamon Press, 1964.) 105s. net.

**T**HE investigation of the many aspects of chemical kinetics in the gas phase is a field so wide that, hitherto, up-to-date detailed surveys have usually been confined to limited branches of the subject. New work in this field is produced at such a rate that even monographs are quickly outdated. Prof. Kondrat'ev's *Chemical Kinetics of Gas Reactions*, which covers the whole of this subject, is as up to date in all the topics it deals with as can reasonably be expected, bearing in mind the time taken to produce a comprehensive work of such a length in the finished form. Prof. Slater, who has edited the translation, has pointed out that new material was added during the course of preparation and this has resulted in the presentation of published data up to about 1960. Formal treatment of basic theoretical machinery required for discussing theories of chemical kinetics has been kept to a minimum. The emphasis that has been adopted has been that of a detailed understanding of elementary reactions, and it is this attitude which is the essential strength of the book.

The book contains chapters on general kinetic rules for chemical reactions; the nature of the observations necessary for the elucidation of chemical mechanism; general theory of elementary reactions, bimolecular reactions, unimolecular and termolecular reactions; photochemistry; reactions in electric discharges; and a full discussion of chain reactions and combustion. The simple kinetic relationships and the approaches to the determination of reaction mechanism are well illustrated by recourse to experimental data. Modern techniques for examining elementary reactions including differential calorimetry, tracer techniques, isotope effects, flames,

electric discharges and flash photolysis are discussed in some detail. While full reference is made to the results of shock tube experimentation, a description of the shock tube itself, which is a very important technique and deserves as much space as many of the other methods considered, is omitted, perhaps for the reason that a number of monographs already exist on this subject.

The chapter on the general theory of elementary reactions illustrates the tone of the book. Of particular interest are the considerations of adiabatic and non-adiabatic processes, deviations from the Maxwell-Boltzmann distribution in chemical kinetics, the construction of potential energy surfaces and the transition state theory, the collision of three atoms and the quantum mechanical treatment of elementary processes including the 'Born method' and the method of distorted waves, and the role of the tunnel effect. The chapters that follow run smoothly from this, so that more than half the book is basically concerned with elementary processes. In more recent years, a large amount of work in combustion chemistry has been directed towards isolating and characterizing the elementary reactions, particularly of atoms and small free radicals, pertinent to combustion mechanism. While any general presentation on combustion must clearly be dominated by chain theory and its application to particular combustion systems, the culmination of such a discussion would be expected to be directed towards an understanding of the elementary reactions of which the overall combustion is comprised. Prof. Kondrat'ev maintains the general theme of his text here. The final two chapters on chain reactions and combustion, which comprise some 200 pages, could well stand as a monograph on their own.

With the exception of the photographic plates, which are poor in quality, the book is very well produced. There is a full list of references and a name index, but the subject index is sparse. It is hoped that these minor points will be rectified in later editions.

The large amount of work that has been carried out in recent years on the investigation of elementary processes, both from the theoretical point of view and experimentally by techniques such as shock tubes, flash photolysis and flow-discharge systems, finds its natural place within the appropriate chapters of Prof. Kondrat'ev's book; for this reason and many others *Chemical Kinetics of Gas Reactions* provides the research worker in gas kinetics with an integrated background of knowledge. It covers a very wide range, it is detailed, and it brings the reader to the forefront of thinking on chemical kinetics in its discussion of modern theories. The price of this comprehensive, lengthy and readable book is very reasonable indeed.

D. HUSAIN

## RESEARCH IN MOTIVATION

### Motivation

Theory and Research. By Prof. C. N. Cofer and Prof. M. H. Appley. Pp. 958. (New York and London: John Wiley and Sons, Inc., 1964.) 94s.

### Experiments in Motivation

Edited by Prof. H. J. Eysenck. Pp. viii+424. (London and New York: Pergamon Press, 1964.) 100s.

**M**OTIVATION is one of the basic psychological concepts which have rather different meanings for the man-in-the-street and for the psychologist. Pressed for a definition, both would probably say (or infer) that in studying motivation one's concern is to explain what causes organisms to behave in the way they do. Divergence occurs in relation to what may be called the level of explanation that is looked for, or accepted; in general the man-in-the-street is probably mostly interested in specific, or specifiable, behaviour acts—the psychologist

rather in explanatory principles, or what Drs. Cofer and Appley call "motivational constructs". As they say: "When we ask questions about the 'why' of behaviour we are seeking information about processes *not* directly observable in an individual's overt actions, or even from his verbalizations about his covert actions. The processes we must study are only indirectly inferable, painstakingly and tentatively, from the events available to direct observation or assessment".

That quotation is from the opening of Cofer and Appley's first chapter. The authors go on to point out that while problems of motivation have been variously "incorporated as subordinate parts of larger areas", or even ignored, the present-day trend is to treat them as "a separate set of problems worthy of independent focus". This is clearly the authors' own predilection—otherwise the book would not have been written. One might be inclined to argue this position, but in the event of this the scope of the research material surveyed is so wide that any implication of narrowing of interest implied by the word 'focus' proves unfounded. This breadth of scope, let alone the complex semantic overtones of the term 'motivation' itself, makes the subject-matter of the book coterminous with that of psychology at large, not excluding systems sometimes regarded rather as related disciplines, such as ethology and psychoanalysis.

A work of this magnitude clearly cannot be summarized; nor, indeed, does the present book lend itself to being read and assessed as a whole. The authors' most individual contribution is contained in their two introductory chapters, and in the concluding chapter, entitled "Toward a Unified Theory of Motivation". Their main concern in that chapter is to demonstrate, with frequent reference back to the main part of the book, that the concept of 'drive', described as a 'hydraulic-like mechanism' stimulated by deprivation states, lacks universality and so becomes a 'liability'. Nevertheless they feel that an equilibration model is in general terms satisfactory, and propose such a model based on the hypothesis of two mechanisms: an *anticipation-invigoration mechanism (AIM)* and a *sensitization-invigoration mechanism (SIM)*. 'Invigoration' is explained (in the former context) in these terms: "...behaviour displays an augmentation of vigour—an invigoration, so to speak—over the level of vigour that would be present in the same stimulus situation without anticipation". It is preferred to 'arousal' (although the terms 'anticipation-arousal' and 'sensitization-arousal' are also used) on the grounds that "it is perhaps not necessary to imply an intervening arousal state". Anticipation can only work, of course, after learning has occurred; cases in which motivated behaviour takes place without previous learning are explained in terms of *SIM*.

The above is an attempt—probably inadequate—to state the authors' views in a close paraphrase of their own words. It is perhaps a pity that they had not presented their case at greater length. As already suggested, the book makes rather heavy reading, and the same applies, to some extent, to the concluding chapter. However, the value of the book as a work of reference up to 1961 or 1962 ('spotty for 1963' is the authors' phrase) is not affected. Particularly remarkable is its extensive bibliography—author index covering nearly 100 closely printed pages.

While Cofer and Appley reject drive, Prof. Eysenck uses it as the basic concept on which the work reported in his *Experiments in Motivation* is based. The book is in two parts: Part 1, extending to nearly three-quarters of the book, reports eighteen experiments with human subjects; Part 2, four studies with animal subjects. Each part is preceded by a short introduction defining the characteristics of the populations from which the experimental ('high drive') and control ('low drive') groups were drawn. It should be noted that, in common with Prof. Eysenck's other compilations with similar titles, the scope

is limited to work carried out at the Institute of Psychiatry or under its auspices.

In fact, in the present instance the range of enquiry is even more than usually restricted, thus belying the claim on the fly-leaf that "the work will be of absorbing interest to all who are in any way concerned with the behavioural sciences, as well as to zoologists, geneticists and anthropologists". In the human experiments 'high drive' subjects were candidates for apprenticeship in the motor industry. The 'low-drive' subjects were apprentices already undergoing training with the same manufacturers. Both groups had the same general background, but they differed in mean age by about eighteen months, and since the 'low-drive' group had in fact passed selection its individuals were somewhat superior in respect of intelligence and other relevant abilities. In addition, the apprentices were aware of the purpose of the experiments, whereas the candidates may well have thought that they were part of the selection battery. No other criterion of drive level appears to have been applied. Is it, then, being tacitly assumed that the candidates' keenness to be accepted will carry over the test situation, while the comfortably secure apprentice will show indifference, even when taken into the experimenters' confidence? Maybe this distorts Eysenck's assumption, but perhaps it is not unfair to suggest that to generalize drive to this extent is to deprive the concept of meaning. In the circumstances it is not surprising to find Prof. Eysenck in his foreword claiming no more than "that there is a certain degree of congruence between theories and results, sufficient to encourage one to continue in this type of work, insufficient to make one feel that issues have been clarified even in the most rough and ready manner".

In the face of such disarming frankness one is almost ashamed to find oneself wondering why it had been considered opportune to publish this large and expensive collection of papers. There is no attempt to draw threads together: the reader is left to collate for himself the conclusions with which each individual chapter ends. Moreover, the book bears every sign of hasty production: much careless writing; innumerable examples of faulty proof-reading; injudicious proliferation of quantitative data (on p. 216 there appears an analysis of variance with 31 components, every one insignificant).

Nevertheless, the book does contain much of interest, particularly in Part 2, which might well have been published separately as a monograph on motivational aspects of rat behaviour. Here selectively bred strains (known as 'reactive' and 'non-reactive') provide experimental and control groups which can be quite explicitly defined, and although the linkage with emotionality, in the human sense, is not altogether convincing, the reader gets a clear impression of the purpose behind the work. One puts the book down with the impression that one has been looking through an enormous collection of journal articles, not all of which would have been accepted, although the animal papers would probably have fared better than the human.

B. SEMEONOFF

## SCIENTIFIC AND TECHNICAL LIBRARIES

### Scientific and Technical Libraries

*Their Organization and Administration.* By Lucille J. Strauss, Irene M. Strieby and Prof. Alberta L. Brown. (Library Science and Documentation: a Series of Texts and Monographs, Vol. 4.) Pp. xi+398. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1964.) 65s.

THIS handbook, by three stalwarts of the special library profession in the United States, is virtually a new and much revised version of *Technical Libraries:*

*Their Organization and Management*, published in 1951 under the sponsorship of the Special Libraries Association. Since the former work appeared, the face of special librarianship has undergone many changes which, in turn, have led to a substantial increase in the number and variety of publications on the subject. Nevertheless, there are still only two comprehensive manuals in the English language—the present volume and the Aslib *Handbook of Special Librarianship and Information Work*—which cover the field at all exhaustively, and the labour that has gone into bringing the earlier Special Libraries Association publication up to date will gain the gratitude of scientific library workers.

It is true that much that can be said about the organization and administration of scientific and technical libraries applies equally to special libraries serving other subjects. The authors have been wise, however, to restrict themselves, since theirs is essentially a practical work of day-to-day reference in which the examination of basic principles is subordinated to factual guide-lines for effective operation. Thus, for example, lists of names and addresses are included wherever possible for publishers, booksellers and subscription agencies. In these matters, while the book is clearly intended primarily for American conditions, its approach is perhaps less narrowly American than its predecessor, and it is good to see prominence given, not only to American publishers but also to some in the United Kingdom, France, Germany, Holland, Italy and elsewhere.

Some of the most effective chapters are those on stock selection, lay-out and equipment, and operating costs, the latter, as the authors recognize, being scarcely amenable to generalized treatment since the unique aspects of every situation make it a case in itself. Even so, they contrive to include range figures for both initial and annual expenditures which should prove a helpful guide to spending ratios on salaries, stock, equipment and services. The considerations to be borne in mind in making the best use of available space are well illustrated by useful diagrams, but rather more technical detail would have been welcome in the sections on lighting, flooring and air conditioning. Every aspect of stock is considered and, while books and periodicals necessarily receive minute attention, there are knowledgeable and thoughtful sections also on patents, standard specifications, translations—with a substantial list of organizations which supply translations—theses, reprints and company reports. The chapter on reference service, incidentally, contains a full and detailed section on patent searching, itself a highly specialized art.

In writing of cataloguing and classification and staff selection, the authors seem to be less at home. Old controversies about training and qualification are by no means dead and, in any event, no two scientific libraries can be counted on to need identical staff. Some imprecision may, therefore, be inevitable but managements, one of the four audiences envisaged by the authors, would certainly welcome a simple and more clear-cut tabulation. Cataloguing and classification are approached from a general, rather than a specifically scientific, library point of view, with the main emphasis on the Dewey and Library of Congress systems and with the U.D.C. relegated to "other general schemes" along with Bliss and Colon. What is inadequately explained is the nature of the many special problems encountered in scientific and technical libraries which frequently make conventional systems inappropriate—and the prodigious difficulties inherent in making a change if a conventional system proves to have been a wrong choice in practice. There is also no reference to the results of the International Conference on Cataloguing Rules held in 1963. In spite of these relatively minor shortcomings, the book is one to which American scientific librarians, and many in other countries also, will find themselves referring over and over again.

L. WILSON

**Synthetic Fibres in Papermaking**

Edited by O. A. Battista. (Polymer Engineering and Technology.) Pp. xi+340. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1964.) 105s.

THERE was a time when it was possible to draw a sharp distinction between paper and textiles, since they were always produced respectively by depositing individual fibres from a wet suspension and by weaving or felting fibres in the dry state. Moreover the raw material for paper was necessarily cellulose fibres, whereas textile fibres could be of animal, vegetable or mineral origin; or, more recently, synthetic. The increasing use of synthetic fibres in paper (and in the present work these also include glass, metal and ceramic fibres) has rendered the above distinction much less clear-cut. Indeed, if products containing more synthetic fibres than paper fibres are taken into account, then the traditional definition of paper would appear to call for revision. These new fibre combinations have resulted in products having striking wet- and dry-strength and electrical properties which make them of considerable interest especially for industrial uses. Applications to the textile, shoe, filter, abrasive, electrical packaging, clothing and household furnishing industries already exist, and the range will doubtless increase as manufacturing technique improves and, more important, as the production cost is reduced. This volume deals with these aspects of the subject, each type of synthetic fibre being the subject of a chapter by an appropriate expert. There are also chapters on web formation, on bonding, structure-property relationships, and on present and future markets.

A chapter on developments in Europe demonstrates the present big lead established by the United States, where the *per capita* consumption of paper is twice that of an average European country. It is claimed that this is the first "hard cover" book on the subject, and this and its American origin and list of authoritative authors commend it to those interested in this new and developing subject. By reason of the wide field of applications involved and the novel nature and possibilities of this branch of 'papermaking', it deserves a much wider public than the paper, fibre or textile technologist.

JULIUS GRANT

**Les Triterpénoides en Physiologie Végétale et Animale**

Par P. Boiteau, B. Pasich et A. Rakoto Ratsimamanga. Pp. xi+1,370. (Paris: Gauthier-Villars, 1964.) 310 francs.

THIS book provides the most comprehensive treatment of the properties of triterpenoids that is at present available. The coverage is unusually wide: it would appear that all references to the chemical, biological and physiological literature concerning triterpenoids published up to 1962 are included, and there are addenda which cover some of the publications of 1963.

The first chapter surveys the various structural types of triterpenoids and interrelates these in terms of their biosynthesis. Then follows a detailed summary of all known natural triterpenoids as well as their naturally occurring derivatives, such as esters and glycosides (saponins). This section also includes numerous indexes of trivial and systematic names presented in terms of common structural features, and lists are given in order of melting-points and specific rotations. The methods of isolation and identification are fully reported and the many methods of degradation which have been used in the structural investigation of triterpenoids are well reviewed. The use of mass spectrometry and optical rotatory dispersion measurement is not adequately covered owing to the very recent publication of much of this work.

The chemist concerned with natural products is often prepared to have his interest broadened, and this is encouraged by this book. Chapters 5, 6, and 7 are con-

cerned with the phytochemistry of triterpenoids, the part that they play in biological processes, and their biotransformation. In a book of almost 1,400 pages, divided into eight chapters, it is perhaps surprising that the last chapter should contain only fifteen pages. However, this is to be expected as it is entitled "Hypotheses of Perspectives".

The book may be likened to a good mixed grill: it certainly contains plenty of meat, but it could cause some indigestion! The sterling equivalent of the price is £22 11s. 0d.

W. D. OLLIS

**Les Oiseaux du Nord de l'Afrique de la Mer Rouge aux Canaries**

Par R. D. Etchécopar et F. Hue. Pp. 608. (Paris: Éditions N. Boubée et Cie, 1964.) 120 francs.

IT is appropriate that the French should give us a comprehensive work on the birds of North Africa, as their ornithologists have for long been active there, particularly in the western part. The authors are distinguished participants in this study, and they have the support of a well-known illustrator in Paul Barruel. The area covered comprises the whole width of the continent, and extends far enough south (approximately 21° N. lat.) to include most of the Sahara. Much of it is desert, but islands, coasts, mountains, and the valley of the Nile provide substantial diversity. The avifauna is essentially palaearctic in character; to have pushed the chosen boundary farther south would have brought in an increasing number of tropical elements. Most of the sedentary species in fact belong, exclusively or otherwise, to the Mediterranean basin as a whole; there are also a few species peculiar to the area, and a few that have infiltrated along the coasts from the south. To these are added the sea-birds and the very numerous migratory visitors from farther north. The book constitutes a valuable source of information on the occurrence and distribution of birds in North Africa, the admirably clear sketch maps giving the main facts for each species at a glance. It is at the same time a useful guide to identification in the field; and there are notes on general behaviour, reproduction (in more detail), and sub-species. No single publication has hitherto covered the whole of North Africa in these respects.

LANDSBOROUGH THOMSON

**Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables**

Edited by Milton Abramowitz and Irene A. Stegun. (National Bureau of Standards Applied Mathematics Series, No. 55.) Pp. xiv+1045. (Washington, D.C.: Government Printing Office, 1964.) 6.50 dollars.

THIS massive compendium is on the lines of the widely used *Funktionentafeln* of Jahnke and Emde, but is more up to date and extensive. There are 29 main sections, from mathematical and physical constants up to the special functions of pure mathematics, mathematical physics, and probability; each section has been prepared by an expert in that field. The text is mainly a collection of formulae, economically displayed on a double-column page, with emphasis on numerical utility. The tables aim at giving at least five-figure information, with intervals allowing for reasonably accurate linear interpolation; the introduction expounds recommended processes when more accurate interpolation is required. Bibliographies are short enough to be helpful, though a little more annotation would not have come amiss. The volume is an obvious item for even a small reference library, and we must thank the U.S. National Science Foundation for making funds available for the preparation of the book, thus enabling it to be put on sale at a price which is very small for its 1,000 closely packed pages.

T. A. A. BROADBENT

## THE SCIENCE OF SCIENCE FOUNDATION

By MAURICE GOLDSMITH  
DIRECTOR

THE 'science of science' is an awkward name but, as it describes accurately what is meant, it has become established. By the science of science we mean the examination of the phenomenon of 'science' by the methods of science itself.

It includes thus: the sociology of science; the psychology of scientists and of scientific work; the economics of science; the analysis of the flow of scientific information; operational research on science; the planning of science: that is, the study and formulation of quantitative observations; the study of the role of science in diverse types of societies; and the relation of science to technology.

The science of science begins to merit the name of science since, although some of the foregoing topics were investigated long ago, it is only now that quantitative treatments can be attempted. This has happened (a) because the volume of scientific activity is now large, taking perhaps 2 per cent of the national income of many countries, so that statistical investigations become meaningful; (b) because techniques of examining more complex phenomena have improved so that many biological, linguistic, economic and sociological topics can be examined quantitatively.

Studies of various aspects of science involve, as in any other branch of science, the collection of appropriate quantitative data; the construction of theoretical models exhibiting the behaviour features isolated from the system under investigation; the propounding of general laws or policies on the basis of the conclusions from examinations of the actual and of the idealized systems, and the comparison of the predictions of these laws with what is actually happening.

The science of science represents the self-consciousness of science. Already much is understood about how science operates. Since science is the factor which determines the rate of change of technology, it is being eagerly seized on by Governments, not only of emergent countries, which wish to increase their rate of development above the *laissez faire* rate. Recommendations need to be drawn up to prevent the repetition of earlier mistakes and to plan scientific growth. These can be found only by generalizing the results of investigations of the interaction of science and society.

Nevertheless, we would not wish the science of science to be just an applied science or the preserve of ministries for science. As in any other field, it will have to be attacked wherever it shows signs of yielding results which will be carried as far as possible for the sake of the understanding which they may give.

An excellent example of one topic in the science of science is Prof. D. J. de Solla Price's investigation of the output of scientific papers, in which he has shown that the rate of publication of papers has been doubling regularly every ten years. The number of scientists has been similarly increasing exponentially. This investigation has been very widely quoted as definite evidence for the feeling that there is a 'science explosion' (like the population explosion, although in this the doubling time is about forty years).

A Science of Science Foundation, accordingly, is being set up to encourage and promote the scientific investigation of national and international science policy and the interactions of science and technology and society.

This was announced in London on October 29 last, the occasion of the publication of the book, *The Science of Science*, a volume of tribute to Prof. J. D. Bernal. This year marks the twenty-fifth anniversary of the publication of his monumental work, *The Social Function of Science*, the first book to present the scientific analysis of science.

The Advisory Committee of the Science of Science Foundation at the moment consists of Lord Snow, Prof. Derek J. de Solla Price (Avalon professor of the history of science and medicine, Yale University), Prof. J. D. Bernal, Prof. Asa Briggs (dean of social studies, University of Sussex), Dr. Alexander King (director for scientific affairs of O.E.C.D.), and Mr. Gerard Piel (publisher of *Scientific American*).

The purposes of the Science of Science Foundation will include the following: To organize an annual lecture (plans are in hand to organize the first lecture in London in April 1965; it will be given by Prof. D. J. de Solla Price on "The Scientific Foundations of Science Policy"); to organize seminars, conferences, or other meetings connected with the aims of the Foundation; to support and initiate research work; to promote the collection of reprints, etc., on science policy and to make them available for analysis.

The resources of the Foundation consist of the royalties on the book *The Science of Science*, and gifts and bequests from other sources wishing to advance the objects of the Foundation.

The first director of the Foundation is Maurice Goldsmith, and the assistant director is Alan Mackay. The address is c/o The Ciba Foundation, 41 Portland Place, London, W.1.

The Ciba Foundation has also generously agreed to provide facilities for six seminars to be held in 1965, and shelf-space to initiate the science of science library.

## THE SCOTTISH RESEARCH REACTOR CENTRE

By DR. HENRY W. WILSON

Director, Scottish Research Reactor Centre, East Kilbride, near Glasgow

THE Scottish Research Reactor Centre at East Kilbride, some 11 miles from Glasgow, is the first of the university reactor centres to be set up in the United Kingdom and was formally opened by Sir John Cockcroft on November 13, 1963. The Centre serves the six universities of Scotland and Northern Ireland—the so-called 'Consortium'—and is financed by a grant made by the Department of Scientific and Industrial Research. This

grant covers running costs up to the end of the university quinquennium in 1967.

University reactors, ranging in power from a fraction of a watt to 1 MW or so, have been in existence for a number of years in the United States and several other countries. Among the reasons for such a facility are: (a) provision of beams of neutrons for physical and chemical investigations; (b) provision of a source of

irradiation for neutron activation and radioisotope production; (c) investigation of radiation effects; (d) provision of a neutron flux for reactor physics lattice structure analyses; (e) training facilities in the fields of reactor physics, nuclear engineering and radiochemistry. To these I would add that it can provide an excellent opportunity for scientists from different disciplines and, certainly in the case of East Kilbride, different universities to meet. On which of the above uses of a reactor are most important depends the final choice of reactor. Other factors are the amount of money available and the nature of the site on to which the reactor must go.

### Early History of the Project

The need for a reactor both for teaching and for research had been felt for some time by the universities in Scotland, and the first meeting was held in May 1959. It was considered that fullest utilization would be ensured by making a joint application by all the universities. Another meeting in December 1959, which was attended by Sir John Cockcroft and Sir Harry Melville in addition to the university representatives, considered among other things the question of where it should go. A site on the ground belonging to the National Engineering Laboratory was suggested and this is where the laboratory was eventually built. It has proved an excellent compromise, as will be made evident later. Another result of the meeting was the decision to make a submission to the Department of Scientific and Industrial Research for a grant to finance the scheme. A technical committee, formed of members from each of the five Scottish universities (the Queen's University of Belfast came into partnership some time later) and chaired by Dr. S. C. Curran, investigated the nature of the needs, considered the choice of reactor and was responsible for the general planning of the Centre. Visits were made to various reactor centres at home and abroad, and eventually the choice of reactor was narrowed down to two-tank type and two-pool type reactors. These were respectively the Hawker Siddeley *Jason*; the *UTR-100*, made by the Advanced Technology Laboratories division of Ideal Standard; *Consort*, designed and built by the Imperial College of Science and Technology and the General Electric Co.; and *Triga*, designed by General Atomics. The choice eventually fell on the *UTR-100* which, with modifications requested by the Scottish universities, seemed best to meet their very varied needs.

Application for a grant was made by the principals of the universities concerned to the Department of Scientific and Industrial Research on August 31, 1960, and in May of the following year it was indicated the submission had been approved along with that of the University of London and the joint application of the Universities of Manchester and Liverpool. However, because of the financial situation, the three schemes were stopped for the time being, and it was not until December 1961 that permission to proceed was given. The machinery was put into motion immediately, and work on the site commenced in the spring of 1962. By January 1963 the reactor hall was sufficiently advanced to allow construction of the reactor to begin. It became critical for the first time on June 24, 1963, and was handed over to the Consortium on September 3. The Centre came into use for teaching and research at the beginning of October, the official opening taking place, as indicated earlier, on November 13.

The remainder of this article will describe the Centre and the reactor itself, and this will be followed by an outline of the first year's utilization and experience.

### Location

The location of the Centre at East Kilbride has brought many valuable benefits. First, I should like to record the excellent co-operation which we have enjoyed with the

Director and staff of the National Engineering Laboratory who have helped us in many ways, particularly with regard to library, photographic, transport and restaurant facilities. The advantages also of building on an already prepared site are obvious—electrical, water, steam and drainage services were already to hand.

Geographically, it would be difficult to choose a more convenient site. A half-hour run by motor-car takes one into the centre of Glasgow, to which East Kilbride is also connected by rapid bus and railway services, while the journey to Edinburgh by car occupies about an hour and a half. The centres of St. Andrews, Dundee, Aberdeen and Belfast can be reached in three hours or so by road, rail or air as appropriate. Students from Glasgow and Edinburgh usually travel to and from the Centre each day by bus, while students from other universities are accommodated in a hotel in the district. This is a practicable arrangement since our courses are normally of one or two weeks' duration. A new hostel which is planned for East Kilbride will be of considerable use for students and research workers alike. Meanwhile, the latter reside in a hotel or sometimes, in the case of a longer stay, in lodgings.

### Reactor Centre Buildings

The layout of the Reactor Centre is shown in Fig. 1 and a general view from the west in Fig. 2. It will be seen that it consists of two main blocks. The reactor block contains a capacious reactor hall, control room, hot chemistry laboratory, hot metallurgical laboratory, plant room, isotope store, instrument wash room and solid radioactive waste store. Outside are two 600-gallon tanks for liquid radioactive waste. The reactor hall measures 80 ft.  $\times$  50 ft.  $\times$  29 ft. high and is served by a 7.5-ton crane which is used to transport the concrete shielding blocks, fuel element cask and for various experimental purposes.

A 1.5-in. pneumatic rapid transfer or 'rabbit' tube connects the hot chemistry and the metallurgy laboratories to the region of highest reactor flux ( $\sim 10^{13}$  neutrons  $\text{cm}^{-2} \text{sec}^{-1}$ ) and feeds into a revolving chamber which can take up to six samples at one time. A 2.25-in. rabbit tube for larger samples runs to the hot chemistry laboratory only. The transit time in each case is about 1 sec.

The hot chemistry laboratory contains stainless-steel fume cupboards and remote-handling equipment, and the metallurgy laboratory is equipped with three Lintott glove boxes. There will also be erected in the reactor block a Collins-type liquefier providing liquid helium for the use of the Centre and others in this area.

The front block, which is joined to the reactor block by the 'link' corridor, contains laboratory, office and other accommodation. The laboratories provide space and equipment for work in a number of different fields of science and technology. These include a radiochemistry laboratory which is used for teaching as well as for radiochemical investigations, neutron activation analysis and the like. There are also another smaller chemistry laboratory and balance room, counting room, physics laboratory, low background room, medical and biological laboratory, teaching laboratory (which can be converted to two laboratories by a folding partition), health physics laboratory, library, lecture room seating between 40 and 50 persons and fitted out with suitable still and motion-picture projection equipment, a conference room and several offices. The equipment in the counting room includes a 512-channel *Laben* pulse height analyser which can be connected to any laboratory in the Centre, including those in the reactor block, by means of coaxial cables terminating in a plug board in the counting room.

The library contains books on nuclear and reactor physics, nuclear engineering, radiochemistry and radiation chemistry, health physics and related subjects. Some two dozen journals are also taken in the foregoing fields. It

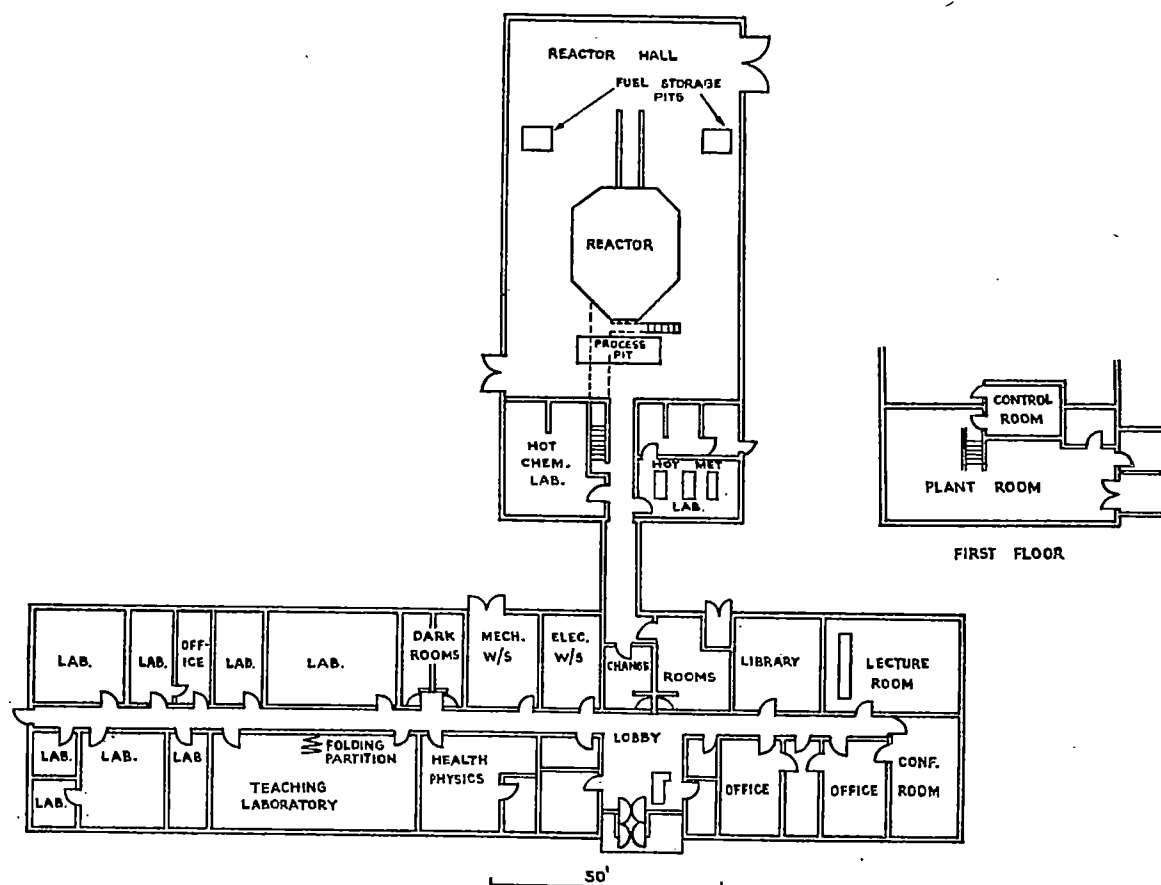

Fig. 1. Plan of the Scottish Research Reactor Centre

Fig. 2. The Scottish Research Reactor Centre

should be emphasized that, through the good will of the National Engineering Laboratory, we are able to make use of their much larger library some 200 yards away.

The laboratory block also contains two darkrooms, a mechanical workshop and an electronic laboratory. Thus it will be seen that an effort has been made to ensure that the research worker (or student) at the Centre will have all

the essential facilities. Although the Centre lies out of the Clydeside industrial area, a run of half an hour takes one into the centre of Glasgow, where most other requirements can be met.

An extension containing two rooms for research workers at the Centre, a technicians' room and a store is about to be built in the space to the left of the reactor hall.

### The Reactor

Fig. 3 shows the reactor, with the control room in the background. The principal features are shown in Fig. 4. The 12 fuel elements are arranged in two parallel rectangular tanks, 18 in. apart, contained in a 4-ft.  $\times$  4-ft.  $\times$  5-ft. graphite block. The flux between the fuel tanks is about  $10^{12}$  neutrons  $\text{cm}^{-2} \text{sec}^{-1}$  and is remarkably uniform over a large volume. The space is penetrated by two through tubes and five vertical holes, one of which measures 6 in.  $\times$  6 in. and can be reached from outside. This is much used for the irradiation of bulky or fragile samples, and it is planned to fit a facility to permit the insertion and removal of samples at full power. The other vertical holes measure 4 in.  $\times$  2 in. The rabbit tubes referred to previously also run into this region. There is also a 4-ft.  $\times$  4-ft.  $\times$  5-ft.-long thermal column which is penetrated by a third through tube plus 15 removable stringers. One of these (to which access can be gained from outside) goes into the core region, the others terminating at a lead gamma shield. Another thermal column, 30 in.  $\times$  30 in.  $\times$  40 in. long, runs to the foot of a water-filled shield tank, 5 ft.  $\times$  6 ft.  $\times$  18 ft. deep. A flux of  $10^9$  thermal neutrons or, with a fission plate, of fission neutrons is available for experimental purposes. The water provides adequate shielding even at 100 kW.

Each fuel element when full consists of 13 plates containing 22 g uranium-235 in the form of 90 per cent enriched uranium dioxide pellets in an aluminium matrix clad in pure aluminium. The reactor power is controlled by four boron plates. Two cores are provided. One, the low-power core, operates at powers up to one watt only and is used for teaching and certain research investigations. Further details of the design and nuclear parameters are available in Report ATL-D-869 "UTR-100 University Teaching and Research Reactor". A paper by J. A. Izatt *et al.* describing the design and commissioning of the reactor is also planned.

Fig. 3. The UTR-100 reactor at the Centre

The architectural design and construction of the centre and of the reactor were supervised by the Ministry of Public Buildings and Works. The reactor itself was designed by Advanced Technology Laboratories of the American Standard Co. and built in conjunction with

Fig. 4. Diagram of the Scottish research reactor (UTR-100) core

G. and J. Weir. Other contractors included Graviners (graphite and lead), J. Crawford and Sons (buildings) and a number of other firms. The cost of the reactor itself was £88,000 and the total cost of reactor, buildings, external services, furnishings and professional fee was £256,335. The original grant from the Department of Scientific and Industrial Research was for £458,300, which also covered running costs until 1967. The grant, which is administered by the University of Strathclyde, has been increased somewhat, principally to take account of increased staff salaries and the provision of other items including a vehicle for use by the Centre.

### Courses

During the first year of operation, that is, until September 30, 1964, 16 courses were held in five main subjects: reactor physics, nuclear engineering, health physics, radiochemistry, and uses of radioisotopes.

These were usually of one or two weeks' duration and were at undergraduate, postgraduate and extra-mural levels. One course had 50 students but, because of limitations of space and equipment, the optimum number is about 20. Students came from all six Scottish universities, Robert Gordon's College, Aberdeen, Heriot-Watt College, Edinburgh, and elsewhere. Two courses on the use of radioisotopes drew scientists from a number of fields. One of these courses was carried out in conjunction with the Western Regional Physics Department.

Held at the Centre this year also were a one-day symposium on the "Uses of Isotopes" (130 delegates were present), a neutron diffraction discussion group and part of a NATO summer school in "Activation Analysis" organized by the Western Regional Physics Department, the University of Glasgow and the Scottish Research Reactor Centre.

It should be emphasized that, although these courses occupied more than half the session, they did not interfere with the utilization of the Centre for research to any important extent.

### Research

It is convenient to consider research activities under different headings. First, the reactor is used to produce beams of neutrons or to study radiation effects as they occur. It is also used to produce radioisotopes, particularly short-lived ones, and to irradiate materials for subsequent study as, for example, in neutron activation analysis, radiation chemistry studies and so on. Finally, the Centre is used for research investigations because of other facilities which it possesses in addition to the reactor.

The first class of experiment involves the construction of special equipment in the reactor hall and beam tubes which is usually more expensive and more complicated than that associated with the second class. As a result the experiments take longer to organize and get under way. The second class more often than not makes use of equipment already available at the Centre or the experimenter's own laboratory. Some of the beam tube experiments planned or actually under way will be described briefly here.

(1) *Neutron diffraction.* A grant has been made by the Department of Scientific and Industrial Research to carry out crystal structure analysis by this method. The equipment is now available and is being assembled at the reactor. The groups primarily concerned in addition to the Reactor Centre staff are the crystal analysis groups at the Universities of Edinburgh, Glasgow and St. Andrews (Queen's College, Dundee). Interest has also been expressed by the Universities of Aberdeen and of Strathclyde. We should like to acknowledge the assistance given by the staff of the Atomic Energy Research Establishment, Harwell, in various ways.

(2) *Neutron focusing.* The very interesting suggestion of P. S. Farago<sup>1</sup> that slow neutrons could be focused and highly polarized by a hexapole magnetic field was followed by a grant application to the Department of Scientific and Industrial Research. This, if successful, will provide a valuable and, at present, unique tool in the fields of low-temperature and solid-state research.

(3) *Radiation chemistry.* An investigation of the effects of radiation on compounds of biological interest by mass spectrometry has been started by Dr. I. Reid and myself in collaboration.

(4) *Cold neutron research.* Prof. Allen and his group at St. Andrews plan to carry out work in this field. The neutron focusing equipment mentioned above would be of value here.

(5) *Noise and oscillator measurements.* These are being carried out by Mr. Izatt and Dr. Scobie, of the Centre staff.

(6) Prof. N. Feather, of the University of Edinburgh, and Dr. Scobie are engaged in the measurement of tritium produced in fission.

(7) *Other measurements.* Among those being considered are an investigation of creep properties by A. I. Smith and D. Murray of the National Engineering Laboratory, further fission investigations using the reactor and nuclear shielding examinations. Other experiments in progress or completed are concerned with flux profiles, control rod worths in various combinations, neutron lifetime and other reactor parameters.

Turning now to the second field of activity—radioisotope production, radiation investigations and neutron activation—we find that such experiments already begun or proposed come from a wide range of disciplines: chemistry, radiation chemistry, radiochemistry, biochemistry; solid state, nuclear and reactor physics; metallurgy, mechanical engineering, zoology, agriculture, medicine, dentistry, physiology and forensic science. Of these, about thirty-five separate projects have already started (and a few been completed) using the Centre's facilities in one way or another, and these have come from most of their fields mentioned here. It is not proposed to go into detail about these researches, but it is clear that the Centre serves a very useful function in this general field.

The third class of research at the Centre which does not make use of the reactor itself arises principally because of the existence of radioactive laboratories, high radioactivity handling facilities and specialized nuclear counting equipment. A prototype whole-body counter has also been developed which could be made mobile, and this would be used in collaboration with Scottish hospitals.

### Staff

The senior staff at the Centre include Mr. J. A. Izatt (deputy director and reactor supervisor), Dr. J. Scobie (reactor physicist), Dr. J. E. Whitley (radiochemist), Mr. K. Boddy (health physicist and safety officer), Dr. G. H. Maconochie (neutron diffraction studies), and myself as director. Other permanent staff include two reactor operators, four technicians (plus three more in process of recruitment), secretary, junior shorthand typist, two janitor-drivers and two cleaners. There are also an M.Sc. and four Ph.D. research students working directly under the direction of Reactor Centre staff and some more M.Sc. students are expected later in the session. These are, of course, in addition to staff and research students from other laboratories.

So many university, Government and other bodies and individuals have helped us that it is not possible, much as I should wish to do so, to name them here, although some have been mentioned earlier. I should, however, like to thank the members of the staff of the Centre for their enthusiastic co-operation and support.

## INTERNATIONAL CONFERENCE ON EARTH SCIENCES

CECIL AND IDA GREEN BUILDING FOR THE CENTER FOR EARTH SCIENCES,  
MASSACHUSETTS INSTITUTE OF TECHNOLOGY

By PROF. H. G. HOUGHTON

Head of the Department of Meteorology in the Institute

**A**N international conference on the Earth Sciences was held at the Massachusetts Institute of Technology, during September 30–October 2, 1964, on the occasion of the dedication of the Cecil and Ida Green Building. This building houses the Institute's Center for Earth Sciences, which is devoted to research and education in geology, geophysics, geochemistry, meteorology, physical oceanography and related aspects of the space and planetary sciences.

The conference consisted of five half-day sessions in each of which three papers were presented by invited speakers. The list of speakers and their titles gives an idea of the nature and content of the conference.

*The Earth's Environment*, Bengt Strömberg (chairman): The Sun and Solar Physics, by Leo Goldberg; The Moon, Planets and their Origin, by Gerard P. Kuiper; The Interplanetary Medium and Solar-Planetary Relationships, by Ludwig F. Biermann.

*Atmospheric Motions*, Robert M. White (chairman): Large-Scale Motions of the Atmosphere, by Edward N. Lorenz; Motions of Intermediate Scale: Fronts and Cyclones, by Arnt Eliassen; Atmospheric Turbulence, by William C. Swinbank.

*Dynamics of the Oceans*, C. O'D. Iselin (chairman): Long-period Phenomena of the Oceans Revealed by Chemistry, by Gustaf O. S. Arrhenius; Large-Scale Circulation of the Oceans, by Henry Stommel; The Spectrum of Waves, by Walter H. Munk.

*The 'Solid' Earth I*, J. Tuzo Wilson (chairman): Long-Term Mechanical Properties of the Earth and Internal Motions, by Gordon J. F. MacDonald; Seismological Information and Advances, by Frank Press; Composition and Phases of the Mantle, by A. E. Ringwood.

*The 'Solid' Earth II*, Sir Edward C. Bullard (chairman): Temperature, Heat Production and Thermal History of the Earth, by Francis Birch; Geochronology and Isotopic Data Bearing on Development of the Continental Crust, by G. J. Wasserburg; Mechanics of the Upper Mantle, by Walter M. Elsasser.

The principal speaker at the conference dinner was Prof. Lloyd V. Berkner.

It is clearly impossible to summarize these fifteen major contributions here, but it is planned to publish them in book form. Selection of highlights from such an extensive and outstanding array is certain to be a matter of personal choice that is best left to the individual readers of the forthcoming volume. I prefer to attempt to assess the present state of the Earth sciences as revealed by the contributions to the conference.

One of the most striking features was that, almost without exception, the speakers addressed themselves to the large-scale problems of the Earth. Much of this is

evident in the titles, and Munk, for example, devoted much of his attention to very-long-period waves in the ocean rather than to surface gravity waves. This seems to be one indication of the approach to maturity of the Earth sciences. These large-scale problems are not new, but they formerly appeared intractable. Attack on them has been made possible by new instruments and data resources and by the relative ease with which masses of data and computations may now be handled on high-speed digital computers. That these advances in knowledge due to technological developments is continuing was indicated by Kuiper's discussion of the lunar surface with the aid of the Mariner photographs and by Biermann's use of data from space probes to reveal the structure and motions of the interplanetary medium. Although it is true that we must observe before we can have a satis-

Fig. 1. The Cecil and Ida Green Building for the Center for Earth Sciences, Massachusetts Institute of Technology

factory explanation, it is equally true that observations by themselves seldom provide explanations. The very fact that hitherto unattainable observations are now being made has had a marked effect, part of which is psychological, in stimulating a new attack on the large-scale problems of the Earth.

Of equal importance has been the application of advances in the basic sciences of physics and chemistry to problems of the Earth. Among these, the application of radioactive isotopes to age determination has had a revolutionary effect on our understanding of the development of continental crusts as pointed out by Wasserburg. Similarly, the better understanding of chemistry at extreme pressures and temperatures and recent knowledge of Earth temperature gradients and heat flow has led to new insights into the composition of the mantle as shown by Ringwood and Birch. This, in turn, has led to the more cogent arguments on convection and continental drift presented by Elsasser and MacDonald. Indeed, in many of the pertinent areas of basic science it is the Earth scientists who are now making the most important contributions. An outstanding example is fluid dynamics and its close relative magnetohydrodynamics, which are basic to a wide variety of Earth science problems. This was well illustrated in the contributions of Goldberg, Biermann, Lorenz, Munk, Eliassen, Swinbank, Stommel and Elsasser. The effects of the essential non-linearity of the hydrodynamical equations were stressed by both Lorenz and Munk, and they, with other Earth scientists, are the leaders in this difficult area.

An interesting side benefit of the increasing dependence on the basic sciences in the exploration of the Earth is the greater ease of communication this has engendered. Particularly in their descriptive aspects, the several Earth sciences have their separate argots which make communication difficult. The common language of physics, chemistry and mathematics that was used by the conference speakers not only made all the papers fully intelligible to the audience of some four hundred but also clarified the essential interdependence of the Earth sciences.

There seemed to be a general feeling among the participants that the conference was an outstanding success.

In large part this reflected the stimulating nature of the papers presented by acknowledged leaders in their fields. Beyond this there was the intangible feeling that the conference was a symbol of the emergence of the Earth sciences as mature fields of science with great promise of further important developments in the near future.

The climactic feature was the dedication of the Cecil and Ida Green Building on the afternoon of October 2 (Fig. 1). The principal speaker at the dedication was Roger R. Revelle, the well-known oceanographer. This handsome and striking 20-storey tower was the gift of Cecil H. Green and his wife of Dallas, Texas. Mr. Green is an alumnus of the Massachusetts Institute of Technology and was one of the founders of Geophysical Services, Inc., which, in turn, led to the creation of Texas Instruments, Inc. Mr. Green was a pioneer in the development and application of geophysical methods for oil prospecting and is an Earth scientist himself. He is a life member of the Institute's Corporation, and both he and his wife have a long-standing interest in education.

The Green Building is constructed of poured exposed concrete with load-bearing walls and is 277 ft. in height—the tallest building in Cambridge, Massachusetts. Each floor contains a free area 48 ft. wide and 93 ft. long between the service rooms, stairs and elevators at either end. This space can be divided in any way desired with simple non-load-bearing partitions. Most of the building is devoted to laboratories, workshops and offices, but there are a number of special features. These include the 300-seat McDermott Hall, the Lindgren Earth Sciences Library, faculty and student lounges, class rooms, seminar rooms and a roof laboratory containing three radar systems and other atmospheric probes. The building houses the Institute's Center for Earth Sciences, which comprises the academic departments of Geology and Geophysics and of Meteorology together with other members of the Institute's staff who are interested in any aspect of the Earth sciences. The aim of the Center is to direct attention to the interdependence of the Earth sciences and their common dependence on the basic sciences through a closely integrated programme of research and higher education.

## ORGANIC GEOCHEMISTRY

By DR. G. D. HOBSON

Department of Geology, Imperial College of Science and Technology, London, S.W.7

**O**RGANIC geochemistry has numerous aspects, and, like many other fields of investigation, its beginnings are obscure. Work in this field has gone on for a long time; the name, however, is of fairly recent origin. The early work was on the composition of coals and crude oils, as well as on the nature of the organic matter of soils. Interest has developed from the determination of bulk elemental composition, to attempts to identify types of compounds or structures, and even specific compounds. Patience, coupled with powerful new techniques and complex new instruments, has led to striking advances in knowledge, especially on the nature of the compounds and structures present. Great as the advances have been, a vast amount of work remains to be done, the problems ranging from the purely academic to the definitely applied.

### Materials

Not only are rocks and oil and natural gas considered, but also substances dissolved or suspended in water. The organic matter may be 100 per cent of the raw substance examined, or it may be a mere trace; it may be of recent origin or even hundreds of millions of years old; it may

be comparatively stable under atmospheric conditions, or readily subject to alteration after collecting the sample, unless carefully preserved until laboratory examination begins.

Weathering, which can extend to considerable depths in some areas, may affect the organic matter in rocks. Ancient rocks at outcrop may become contaminated to a small extent by organic matter of recent origin. Petroleum and aqueous solutions of organic substances can move through permeable rocks, and so be found in rocks other than those in which they were formed or in which they first accumulated.

### Mechanisms and Conditions

Identification is not the only aim of organic geochemistry; there are important cases where explanation is the ultimate goal. Consequently, substances have been subjected to various treatments, the rate of change and the products being examined.

During investigations of mechanisms and allied matters a variety of problems arise. What degree of simplification should there be? What parameters should be investi-

gated? In some cases the choice of a suitable organic substance, or starting point, is reasonably simple; in others there is decidedly less certainty about what it should be. The experiments and auxiliary investigations may lie mainly within the realm normally attributed to chemistry, yet in this type of examination in particular, team-work is imperative, both in planning and interpretation, with an adequate contribution from the geologist. A chemical or a physical determination can be a full answer to some questions; in other instances the significance and meaning of the determination have to be decided against a background of data and ideas which may be assignable to some other branch of science.

Sometimes the probable range of physical conditions in Nature's laboratory can be estimated with moderate accuracy; but when igneous intrusions have played a part the maximum temperature and pressure may be much less certain, with the former exceeding the values attained in a sedimentary rock merely by depth of burial. Although temperatures and pressures, such as are applied in Nature, can usually be attained experimentally, time cannot be matched.

Except when igneous activity is involved the temperature and pressure to which the organic matter is subjected will rise slowly in Nature. Rocks now at outcrop have returned to a low pressure and temperature. Some rocks will have been subjected to more than one phase of rising pressure and temperature.

The environment of the reactions in Nature includes inorganic matter, which is often far more abundant than the organic matter, and commonly it is possible for fluids, with dissolved matter, to enter and to leave the reaction site. Water is invariably present, and in many cases the inorganic mineral matter is fine-grained and contains clay minerals. Soils and recently deposited sediments have micro-organisms, and may also be worked in some measure by larger organisms in the course of burrowing or feeding. Low-intensity radioactivity may exist in the deposits.

The components of living organisms vary in their resistance to change when incorporated in sediments on death, and change is also dependent on the sedimentary environment.

### Some Methods and Results

Fractionation is often the first step in characterization. For coals, petrographic examination and painstaking picking may be the preliminary operations<sup>13</sup>; whereas with other materials solvents or chromatographic techniques may be used. Beyond this stage the resources available, the state of knowledge and the nature and amount of the material available determine the extent to which identification of specific compounds can be made<sup>6</sup>. An example of what can be achieved by skill, patience and extensive resources is the examination of the Ponca City crude oil in which, over a period of more than thirty years, 234 compounds (230 hydrocarbons and 4 sulphur compounds) have been identified; these compounds account volumetrically for nearly half the crude oil<sup>12</sup>.

A desire to process large numbers of samples or relatively intractable materials may lead to the use of an empirical approach and the use of methods which measure something not very clearly specified in every case, yet which, in some senses, give quantitative data. Alternatively, a relation may be observed between the amount of organic material of interest and some other more easily measured parameter, and thereafter measurements of the latter parameter are used to build up a picture of the amounts of the organic material present in what is believed or assumed to be the same type of rock. In one area, radioactivity and other logs have been made in boreholes in an oil shale series in order to estimate the yield of oil,

thereby avoiding the costly operation of taking cores which have afterwards to be assayed, a somewhat time-consuming process for detailed coverage<sup>8</sup>. Elsewhere the nitrogen content, or the organic carbon content, has been used, with a multiplying factor, to estimate the total content of organic matter in rocks<sup>16</sup>.

In sinking wells for oil and gas, coring is normally slower and more expensive than drilling, and it is impracticable to recover cores without the risk of some disturbance of any liquid or gaseous organic content. Moreover, the cores, on reaching the surface, have to be preserved by special means, if further changes are to be avoided before laboratory examination can be undertaken. Logging techniques have been developed which give an almost continuous record of the low-molecular-weight paraffins in the rocks penetrated, either by detecting the hydrocarbons which have entered the drilling mud from rock broken up by the bit, or which have escaped into it later from rock fragments<sup>21</sup>. In addition, rock fragments brought to the surface by the drilling mud may be separated and subjected to sub-atmospheric pressure to release gas which is detected and can be analysed chromatographically.

Recently the production of hydrocarbons from behenic acid by heating at 200° C in the presence of water and a clay mineral has been reported<sup>19</sup>, and alterations to hydrocarbons and crude oils by radioactivity in the presence of limestone, quartz sand or clay minerals, with and without water, have been investigated<sup>1</sup>. Radiolysis increased the amount of resins and asphaltenes in crude oils. There have been renewed investigations of the rate of alteration of organic matter in rock on heating<sup>1</sup>.

Particular types of organic matter have been used as indicators of conditions or sources. Thus the presence of porphyrins has been taken to point to anaerobic conditions of deposition and to only moderate temperatures in the subsequent history of the rock<sup>4</sup>. Some compounds or types of structure may not, however, be quite such good pointers to the kind of source organism as was once thought to be the case. Thus, porphyrins with the phyllo spectrum are derived from chlorophyll, but those with the aetio spectrum may be from the haemoglobin series, or from plants<sup>7</sup>. Electron-spin-resonance measurements on coal and carbonized coal samples have been used to estimate the temperature attained by a coal in the vicinity of an igneous intrusion, and similar measurements have provided support for the view that the origin of fusinite involves carbonization<sup>9</sup>.

Investigations of the ratios of the stable carbon isotopes of organic matter in recent sediments have shown trends in values in going from freshwater to marine deposits<sup>14</sup>. This kind of observation may be capable of indicating environment in ancient deposits. Recently an extensive compilation of data on carbon isotope ratios has been made, together with a summary of the hypotheses put forward to explain the ratios<sup>15</sup>.

Bacteriostatic substances have been detected in coals, and the preservative effects of materials in peat bogs<sup>4</sup> have been revealed spectacularly by the discovery in them of corpses of considerable antiquity. The occurrence of coal deposits is controlled by factors different from those which apply in the case of oil. Accordingly, geochemical investigations may not be directed towards the discovery of new deposits, but rather towards the better utilization of coal and to purely academic problems.

Sometimes the amount of organic matter in a sediment, and not its exact nature, is of practical importance. When the Oxford Clay is used for brick-making by one process the amount of organic matter markedly affects the quantity of coal required in the kilns.

The boundaries of organic geochemistry are diffuse, a description which applies also to other subjects. It may, therefore, be in order to consider certain aspects of carbonate sedimentation in which organisms may be, or

are known to be, involved. In addition to shell and skeleton building, pelleting activities and burrowing can lead to some measure of mixing of organic matter with carbonate minerals, and it has been suggested that the rapid multiplication of diatoms may lead to the precipitation of calcium carbonate from sea-water as 'whittings'<sup>17</sup>. There are probably other instances, or types of rock, in which the effective organic agent or substance is not apparent in the deposit.

During recent years, American oil companies, especially, have paid considerable attention to organic geochemistry. Fundamental investigations have been undertaken<sup>2,8</sup>, because these may well contribute eventually to the more effective search for new oil fields. In Europe, too, there has been similar, yet decidedly less, activity<sup>10</sup>. Universities and research institutes have also carried out investigations in organic geochemistry, the departments involved varying from place to place. Some problems require materials from distant places, or samples that are expensive to obtain. Other investigations can be made on materials that are decidedly easier to acquire. The facilities needed for effective work depend on the problem, and range widely in cost and complexity. Scope exists for many more teams to enter this fascinating field of investigation, and it is to be hoped that in the cases of university departments detailed and fundamental work

will be given preference, even though the facilities may be more limited than in major industrial organizations.

## RELATIONSHIP OF BIOLOGICAL REGULATORY MECHANISMS TO LEARNING AND MEMORY\*

By DR. SAMUEL H. BARONDES

Department of Psychiatry, McLean Hospital, Belmont, Mass., and Harvard University

**T**HERE have been a number of recent suggestions concerning the possible involvement of various biological regulatory mechanisms in the process of memory storage. These proposals have considered such reactions as nucleic acid synthesis<sup>1-3</sup>, protein synthesis<sup>4,5</sup>, enzyme induction<sup>6,7</sup>, and antibody formation as possible models for the biological basis of this process. The specificity of these proposals has tended to obscure their underlying agreement that a general biological regulatory mechanism has probably been adapted in the nervous system to mediate its function of memory storage. Stated in this manner, this proposition seems almost self-evident. Since such widely differing cells as bacteria and mammalian liver cells share similar regulatory mechanisms, why should not all mammalian cells, including neurones, be governed by the same processes of adaptation and control? The major difference between neuronal and other tissues is the necessity, not only for regulation of each individual cell, but also for precise regulation of subtle intercellular relationships which establish the neuronal circuits which control behaviour. It seems reasonable to assume that such regulation makes use of the same biological processes that are used for the control of other specialized functions in other tissues.

This article attempts to relate our present understanding of biological regulatory mechanisms to the problem of memory storage. The emphasis here, like that in a recent paper by Dingman and Sporn<sup>8</sup>, will be on a general approach to the problem. Nevertheless, a specific point of view will at present be favoured—that memory is based on the development of new synaptic connexions, and that protein molecules are involved in this process. Experiments relevant to this notion will then be considered in the context of this framework.

The proposal that learning and memory are based on the development of new functional synaptic connexions has been maintained since the demonstration of the nature and significance of this structure<sup>10</sup>. From the point of view of this discussion, a feature of synaptic morphology which should be particularly noted is that it is consistent not only with the presence of many functional interneuronal connexions, but also with the existence of 'potential' connexions. Thus, of the hundreds of synaptic knobs in close proximity to a given neurone<sup>11</sup>, only some may be involved in functional synapses. Other synaptic knobs may not, however, be in sufficient 'contact' with the post-synaptic neurone to participate in its activation, but may, because of their proximity to the post-synaptic neurone, be considered to be 'potential' connexions. Small changes may be made in such 'potential' connexions in the process of learning, and the resultant functional connexions may well be the basis for memory storage. It is important to realize from this that the change which is the basis of memory may not necessarily be effected by a major process which builds up a whole neuronal connexion. Rather, it may be due to so subtle a process as the alteration of a single critical molecule with consequent conversion of a 'potential' synaptic connexion into a functional one. Whether by subtle or major change, however, a new synaptic connexion seems crucial for memory; and the molecular mechanisms considered in this report will all be oriented towards explaining how this could be brought about. From this point of view, the molecule involved in memory is not believed, in itself, to contain the specific information which has been stored. Rather, the new synaptic connexion which is established by this biological alteration is felt to be the repository of the psychic event.

Before considering the specific molecular mechanism which may be involved, several more general aspects of the problem will be briefly noted.

\* Substance of a lecture given at the symposium on "Mechanisms and Disturbances of Memory", 72nd Annual Convention of the American Psychological Association, September 7, 1964.

The first of these is related to the overall mechanism by which a new synaptic connexion might be effected. A number of investigators have felt that repeated activation of a neurone might lead to the formation of synaptic connexions with other neurones on which its processes terminate<sup>10</sup>. Support for this comes from the observation that use of a neurone may lead to biochemical alterations in the nerve cell body<sup>1</sup> and also may stimulate the outgrowth of terminal neuronal processes<sup>12</sup>. Sharpless<sup>13</sup> has recently questioned this concept on the grounds that use of many of the same neurones occurs in both learning and extinction with different behavioural results. This criticism seems, however, to be really directed at our ignorance of the mechanisms of reinforcement and extinction. Our understanding of these phenomena is too meagre to answer questions about the nature of the neuronal circuitry between stimulus and response. But the biologist has often done useful work by tentatively ignoring phenomenological complexities and focusing rather on what he can readily envisage and explore. In this case, synaptic connexions seem a likely basis for memory, and activation seems to lead to biological alterations which could be related to the formation of these connexions. Although we do not understand reinforcement, we need in no way be deterred from making plausible proposals based on what we do understand about biological regulatory mechanisms.

A second feature which should be noted is the apparent existence of an interval between a learning experience and its permanent deposition in the nervous system. This is suggested by experiments in which retrograde amnesia has been produced by administration of electroconvulsive shock following learning. The interval following learning during which a convulsion can produce amnesia has varied in different experiments, from hours<sup>14</sup> to seconds<sup>15</sup>. Beyond this period, the memory is considered to have been 'consolidated', that is, deposited in a more permanent form. Since the delay between experience and 'consolidation' seems so variable, its duration has not as yet provided a clue to the type of biological process which might be operative during this period. That there may be different mechanisms for 'short-term' and 'long-term' storage is, however, suggested. Our commitment to the concept that memory storage is based on the development of new synaptic connexions extends to all phases of this process. But the specific reaction involved may well be different at different times after experience, so that the quest for a single change as the sole basis of memory might prove to be naïve.

In recent years, two major processes which regulate cellular function have been discovered. The first, which will be referred to as 'biosynthesis', has been primarily studied in bacteria, but a great deal of evidence suggests that a similar process is operative in mammalian cells. Enzyme induction is an example of this, but there is no reason for believing that the synthesis of proteins with non-enzymatic functions is not also regulated in a similar manner. In the case of enzyme induction, the substrate of a particular enzyme stimulates the biosynthesis of a specific molecule of messenger RNA<sup>16</sup> the structure of which is dictated by the inherited DNA of the cell. This RNA contains the information for the biosynthesis of a specific protein which can, in turn, react enzymatically with the substrate. The cell, in response to the substrate, thereby makes a protein which can utilize or otherwise alter the substrate. A similar process is believed to be involved in the regulation of mammalian liver cells by adrenocortical steroid hormones<sup>17</sup>. In this case, the hormone may stimulate the biosynthesis of a number of different enzymes which in turn alter some aspect of the metabolic activity of the cell. It should be clear that 'messenger' RNA synthesis is believed to be involved in enzyme induction because its rate of synthesis controls, in some systems, the rate of specific protein synthesis.

In mammalian systems it remains possible, however, that the rate-limiting step in protein synthesis may not always be the synthesis of new 'messenger' RNA. Therefore, even if protein synthesis is needed for memory storage RNA synthesis may or may not be involved as a necessary antecedent event.

A second regulatory mechanism will be referred to as a 'molecular rearrangement'<sup>18</sup>. Here a specific substance, whether substrate or hormone, or other 'regulatory compound' causes a structural alteration in a specific protein molecule, thereby altering its function. A marked functional change is, thus, produced—not by the biosynthesis of a new protein, but rather by the structural alteration of a pre-existing protein. As in the case of biosynthesis, there is no reason to believe that this regulatory mechanism is confined to altering enzymatic activity. Structural or receptor functions of protein molecules could indeed be regulated by a similar mechanism, but have been more difficult to investigate since they cannot be isolated and functionally evaluated as readily as can an enzyme.

It should be noted that both these regulatory mechanisms act on proteins. It is because of our familiarity with these processes, and because of the myriad of structural, enzymatic, receptor and regulatory functions of proteins, that at present it seems most likely that this class of molecule is involved in the cellular alteration which constitutes memory. This does not exclude the participation of other classes of molecules in this process. New or pre-existent RNA may be required for new protein synthesis. Lipids, or other molecules, may be required to stimulate or maintain a change in protein structure. For that matter, processes which are at present unknown may, of course, be involved. But the participation of proteins seems, on the basis of our present understanding of biological regulatory mechanisms, to be extremely likely.

If we are prepared to consider that memory storage is mediated by the same general regulatory mechanisms as are other adaptive alterations in cellular function, it seems reasonable, from the foregoing considerations, to maintain that the new synaptic connexion may be formed either by biosynthesis or by molecular rearrangement of a protein. The stimulus for such a change may be a neurotransmitter substance, or it may be a material released during neuronal activation which does not function as a neurotransmitter. The resultant change may occur either in the pre-synaptic neurone or in the post-synaptic neurone, or in both. The post-synaptic neurone may seem a more likely site because its dendrites and cell membrane are physically closer to the regulatory processes of the neuronal nucleus than are the axonal terminals of the pre-synaptic neurone. But it remains quite possible that the new connexion is based on an alteration in the axon terminal which is not dependent on control by the nucleus. Formation of a new functional synapse may or may not be based on an increased proximity between the processes of the neurones involved, since functional contact between these may be produced, not only by physical closeness (produced by biosynthesis or by 'stretching' due to molecular rearrangement), but also by alterations in transmitter or receptor functions. The change may be in an enzyme which controls the synthesis of, release of, degradation of or permeability to a transmitter substance. The change may also be in number or configuration of receptor proteins. Some of these possibilities are listed in Table 1. Both the suggestions of others and other unemphasized mechanisms are represented in this tabulation. So far, there is no basis for choosing between the alternatives listed.

One of the puzzling aspects of a memory is its permanent deposition within a nervous system which, except for its presumably immutable neurone DNA, is apparently being degraded and re-synthesized at a fairly rapid rate. The

Table 1. SOME WAYS A NEW SYNAPTIC CONNEXION MIGHT BE ESTABLISHED

Neurone changed		Mechanism	Likely molecule
Pre-synaptic	Proximity increased	Outgrowth of axonal process	
	Proximity same	Increased synthesis of transmitter	
		Altered release of transmitter	
	Proximity increased	Outgrowth of dendritic process	Protein ('biosynthesis' or 'molecular rearrangement')
Post-synaptic	Proximity same	Increased synthesis of receptor	
		Increased sensitivity of receptor	
		Increased permeability to transmitter	
		Decreased degradation of transmitter	

fact that the molecules of the nervous system are subject to the process of 'turnover' has necessitated the notion that the molecular change in memory can reproduce itself, that is maintain its permanence by some form of self-replication. This has suggested to Schmitt<sup>3</sup> that an RNA molecule, which could conceivably direct the synthesis of identical RNA molecules, is involved in memory storage. Such a conclusion appears unnecessary. Instead 'self-replication' may be explained by the 'trophic' properties of a newly established connexion. It is well known, from investigations of the behaviour of cells in tissue culture, that removal of a cell from its normal neighbours may result in profound morphological and biochemical changes. Intercellular 'contact', therefore, seems of great importance in regulating cellular activity. A similar mechanism may be responsible for maintenance of a new synaptic connexion, once it has been established. Thus, the greater 'contact' between the pre- and post-synaptic neurones produced by the initial event in memory deposition may stimulate one, the other, or both of these cells to repetitive biosynthetic activity which results in the maintenance of the connexion. This 'maintenance phase' may require a different type of biochemical process than that required for establishing the connexion. Indeed, although initial establishment of the connexion could be based on either biosynthesis or molecular rearrangement, it seems likely that maintenance of the connexion involves some type of biosynthetic activity.

A number of different experiments have been considered to approach the identification of the specific biological regulatory mechanism involved in memory storage. These will be briefly evaluated in the light of the preceding discussion. One type of investigation has sought to implicate RNA in this process by observing the effect of yeast RNA on learning. It has been shown that injections of yeast RNA enhance learning and memory in old people with cerebral arteriosclerosis<sup>19</sup> and accelerate acquisition of a conditioned avoidance response in rats<sup>20</sup>. Such experiments have not as yet, however, contributed to our understanding of the molecular basis of memory storage since the manner in which the injected RNA works is at present obscure. Even if we assume that a portion of the nucleotide degradation products of the injected material cross the blood-brain barrier and enter the brain, they could operate in such diverse ways, as increasing the pool of adenosine triphosphate or guanosine triphosphate which participate in many reactions, or influencing the formation of such important compounds as uridine diphosphoglucose or cytidine diphosphotriglyceride which are required for sugar or lipid metabolism, respectively. To argue that they are acting by influencing RNA synthesis seems unfounded. The interpretation of these results is rendered even more

uncertain by the finding (Cohen and Barondes, unpublished) that injection of mice with highly purified yeast RNA does not influence their learning to avoid shock by escaping through a white, rather than a black, door.

A second approach was taken by Hyden and Egyhazi<sup>21</sup>, who have reported alterations in the composition of nuclear RNA in vestibular neurones following learning of a balancing task. This interesting observation underscores previous demonstrations of altered RNA metabolism in activated neurones<sup>1</sup> which has suggested that such alterations may be related to the learning process. It does not, however, successfully distinguish a general response due to activation from a presumed specific response due to learning.

A third approach to this problem has adapted inhibitors of protein or RNA synthesis to examine the role of these processes in learning and memory. RNA synthesis from a DNA template can be completely inhibited by actinomycin D (ref. 22). Administration of analogues of the precursors of RNA, such as 8-azaguanine, may lead to the incorporation of these compounds into RNA, thereby causing the RNA to function abnormally. Administration of puromycin can markedly inhibit the biosynthesis of protein<sup>23</sup>. Each of these inhibitors has been used in an attempt to identify the participation of protein or RNA synthesis in learning and memory.

Dingman and Sporn<sup>24</sup> injected rats intracisternally with 8-azaguanine and found that this resulted in impaired acquisition of a swimming maze. This finding, and that of Chamberlain, Rothschild and Gerard<sup>25</sup>, who investigated the effects of this compound in a somewhat different situation, indicate only, as suggested by Dingman and Sporn<sup>24</sup>, that RNA synthesis may be required for normal neuronal function. They do not imply that RNA synthesis is specifically required for memory storage. This latter possibility is questioned by the experiments of Barondes and Jarvik<sup>26</sup> in which actinomycin D failed to influence conditioning of a passive avoidance response, despite the fact that cerebral RNA synthesis was inhibited by 85 per cent of animals injected with this compound. Interpretation of the experiment with actinomycin D is, however, limited since memory had to be tested within hours after training, to avoid the period of irreversible toxicity which followed shortly thereafter. Because of this, participation of RNA synthesis in the long-term 'maintenance' process of memory storage may not have been tested by this experiment, although at the time the animals were tested the learned response was no longer susceptible to the retrograde amnesic effect of electroconvulsive shock. The only conclusion which we can reach about the experiments with inhibitors of RNA synthesis is that there is at present no definite evidence that this process is specifically involved in memory storage.

Flexner, Flexner and Stellar<sup>5</sup> have reported that when mice were injected intracerebrally with puromycin their memory of the solution of a maze learned days or weeks previously was obliterated. This experiment suggests that protein synthesis is required for memory storage, despite the previous finding<sup>4</sup> that subcutaneous injections of puromycin given before, or one day after training, had no such effect. The long period after learning during which puromycin is effective suggests that protein synthesis may be required for the 'maintenance' of the new synaptic connexion. It does not, however, indicate that protein synthesis is necessary for the initial event in the formation of the new connexion which can still, on the basis of what is at present known, be explained by the process of molecular rearrangement.

It should be clear from this discussion that we are now in a preliminary phase of investigation of the complex problem of the biological basis of memory storage. It is anticipated that our growing understanding of biological regulatory mechanisms will prove indispensable

to further investigations in this difficult interdisciplinary area.

## OBITUARIES

### Prof. W. H. Pearsall, F.R.S.

PROF. W. H. PEARSALL, who died on October 14 at the age of seventy-three, was a versatile botanist and a man of whom it was said that he had become a legend in his own lifetime.

He was educated at Ulverston Grammar School and the University of Manchester. After service in the First World War he joined the staff of the University of Leeds, eventually becoming reader in botany. In 1938 he was appointed professor of botany in the University of Sheffield. From 1944 until his retirement he was Quain professor of botany in University College, London. He continued his association with the College as emeritus professor and honorary research associate. In 1940 he was elected a Fellow of the Royal Society, which he served in many ways, including two terms on its Council. In 1963 he was awarded the Linnean Society's Gold Medal.

Pearsall's father was an amateur botanist and ecologist and a lover of the Lake District. It was during holidays there that Pearsall began to acquire his unique knowledge of the district. He and his father began the study of the aquatic macrophytes of Esthwaite Water and other lakes in 1913. After the War they made a thorough investigation of the planktonic algae. Pearsall was also mapping the vegetation of the fen at the head of Esthwaite Water. More than forty years later he made his last, unpublished map. The North Fen, now a Nature Reserve, is the best-known fen of its kind in Britain. From these investigations came a series of classical papers about the development of the English Lakes and their vegetation, together with his interest in the chemistry of underwater soils and post-glacial history. Meanwhile he was also carrying out laboratory investigations on plant physiology which were both valuable in themselves and threw light on the ecology of the plants concerned. He did notable work on the growth of *Chlorella*, which he also used as an ecological tool to elucidate the growth of algae in lakes. The work he did on the physiology and ecology of aquatic plants has been a constant source of inspiration to workers at the Freshwater Biological Association and elsewhere.

Pearsall edited the *Journal of Ecology* for several years, and, at the time of his death, was still one of the editors of the *Annals of Botany*. He was also a trustee of the Society of Experimental Botany. He exerted special influence on the growth of the Freshwater Biological Association, the Nature Conservancy and the Institute of Biology.

A founder member of the Freshwater Biological Association, he acted as honorary director during 1931-37 and chairman of Council from 1954 onwards. Few have done as much as he did to bring the Association from its humble birth in a period of economic depression to its

present position as one of the most famous bodies of its kind in the world. His influence on the members of the staff extended into every aspect of their work, including the ecology of fish, in which, perhaps, he had a special interest from his love of fishing. In his artistic appreciation of Nature—he was a good painter in water-colours—lay part of his wonderful insight into the broader aspects of ecology. He was a natural choice as a Charter Member of the Nature Conservancy. The unique position this body holds in the world to-day is, to a large extent, the result of the untiring efforts he made on its behalf. Characteristically his influence was felt both in the sphere of high policy and among the younger scientists who joined the Conservancy. He also made a notable contribution to the protection of wild life in Africa by his *Report on the Ecological Survey of the Serengeti National Park, Tanganyika* (1957). His influence on the Institute of Biology, of which he was chairman in 1957-58, was also profound, while he was the first vice-president of the Council for Nature. He was consulted officially on innumerable biological matters, but it may not be generally known how often he was also consulted unofficially.

Pearsall was the most understanding and generous of friends. He was always good company, and many will remember with affection the twinkle in his blue eyes which heralded the start of one of his stories. To be with him in the field, especially on the hills he loved so much, was pure joy. Something of this can be felt when reading his *Mountains and Moorlands* (1949). His influence on younger workers was immense, notably in the period when he was at University College, London. He could be obstinate, even exasperating; yet one of his most wonderful characteristics was that it was out of disagreement that some of the most fruitful researches of his colleagues were likely to come—much to his delight. Their regard for him grew all the time, irrespective of whether they agreed with his ideas or not. Moreover, his hypotheses were by no means always incorrect; they might equally be too novel for people to appreciate their value at first.

It is no wonder that Pearsall was so highly respected and widely loved, or that he will be so sorely missed. His wife and two sons who survive him will receive sincere sympathy in their loss from a host of friends and colleagues.

J. W. G. LUND

### Prof. Vincent Nechvile

PROF. V. NECHVILE, whose death was reported in July of last year, was born in Prague on April 10, 1890. Like many other astronomers of his generation, Prof. Nechvile entered our science as a mathematician. Soon after his doctorate at the Charles University (as a pupil and later assistant of the late Prof. Karel Petr), his career was interrupted by four years of the First World War, most of

which Nechvile—the gentlest of persons—spent in the uniform of a cavalry officer. His scientific career did not really blossom out until, in the post-war decade, a grant from the French Government enabled him to spend several years at the Observatoire National de Paris, for it was there that Nechvile developed all his interests, sympathies, and inclinations to which he remained faithful throughout his scientific life.

Under the influence of Prof. Andoyer, Nechvile's mathematical interests turned to the restricted problem of three bodies; and he was the author of the well-known transformation of co-ordinates in the elliptic case (that is, when the two finite masses describe elliptic orbits) which has become the basis of most subsequent work on this subject. Collaboration with George Willis Ritchey (the creator of the large reflectors at Mount Wilson, who was also working in Paris at that time) led Nechvile to study geometrical optics. His work on the theory of the Ritchey-Chrétien catoptric systems constitutes a fundamental contribution to the subject (alas, but little known, as most of it was published in Czech).

However, Nechvile's principal work at Paris was in the field of stellar proper motions. In the 1880's, the Henri brothers secured more than a hundred negatives with their prototype of the 'normal astrograph' of the *Carte du Ciel*, with sufficiently long exposures to record the positions of stars down to the 14th magnitude. At the encouragement of Prof. Deslandres, then director of the Paris Observatory, Nechvile repeated these photographs with the same instrument after a time lapse of more than 40 years; and from the combined material derived proper motions of almost 3,800 faint stars in certain areas distributed widely all over the sky—probably the largest homogeneous measurements of proper motions of faint stars then available.

This work, which earned Nechvile the Lalande Prize of the French Academy of Sciences, paved the way for an academic career at home. On his return to Prague in 1930, Nechvile became docent of astronomy at Charles University (followed by a recommendation to honorary professorship in 1939), which together with the position of astronomer at the Czechoslovak National Observatory, he held until his retirement in 1960. During his years in Prague, Nechvile's scientific interests continued in the same fields; but increased teaching and administrative duties at the Observatory (Nechvile became acting director during a part of the difficult years of the Second World War) left him but little time for research. This was especially true in post-war years, which for him became a time of increasing solitude. He never married (twice death intervened to deprive him of the prospective companions); his family dispersed (his only brother found his final resting place in England), and so did many of his pupils—of whom I had the privilege of being one. He died in Prague last summer, aged seventy-four, alone,

so that even the exact day when death claimed him remains unknown.

Vincent Nechvile will be remembered with warm affection by all who knew him, as the type of man—so increasingly rare in these days of competitive life—to whom Horace's epithet "*integer vitae scelerisque purus*" can truly be applied. Always kind and gentle, he instinctively shied away from any situation which could have compromised his principles; it is doubtful if he ever harmed anyone, or made a single enemy in his lifetime. Although of somewhat frail health, his strikingly youthful appearance did not desert him until almost the end; and as such he will live in the memories of all who remember him from the pre-war years.

ZDENĚK KOPAL

### Prof. W. Klüpfel

In the death of Prof. Walther Klüpfel on September 16, 1964, at the age of seventy-six, Germany lost an outstanding geologist.

Klüpfel was born on May 28, 1888, in Heidelberg, Germany. He received his training in geology at the University of Heidelberg, where he graduated as a Ph.D. He was appointed as lecturer in the Geological and Palaeontological Institute, University of Giessen, Germany. In later years he held the chair.

During the First World War, Klüpfel was sent to France to work on the water-supply for the German Army. This was resumed during the Second World War, which led him to Jersey, Channel Islands, then occupied by the German Forces. There he remained for three years, during which time he did much valuable field-work in the Island. After the War, he was transferred to the University of Marburg, Germany. The University of Giessen had been heavily bombed.

Since 1921, and in the following years, Klüpfel's research work on volcanic formations convinced him that there is a fundamental difference between Pre-Quaternary volcanoes and Recent and Diluvian volcanoes. His extensive investigations and results were published in Germany. One of these papers was translated into English: "On the Old Type Volcanoes and the New Type Volcanoes and their Origin" (1941).

On his retirement from the chair, with his great devotion to geology, Klüpfel continued his field-work, especially in Jersey. In 1962 he once again visited the island.

Geology to Klüpfel was a whole life's work. He was an exemplary teacher, both in the field and as a lecturer. He was very much liked by his students, although very exacting; he could be most humorous, laughed heartily, and had many sterling qualities. I will remember him with gratitude, affection and admiration.

He died at his home in Giessen, Germany, and is survived by his second wife.

M. CASIMIR

## NEWS and VIEWS

### The Royal Society: Vice-presidents

THE President of the Royal Society, Sir Howard Florey, has appointed the following vice-presidents for the year ending November 30, 1965: Lord Fleck, treasurer of the Royal Society, formerly chairman of Imperial Chemical Industries, Ltd.; Sir William Hodge, physical secretary of the Royal Society, Master of Pembroke College and Lowndean professor of astronomy and geometry in the University of Cambridge; Prof. A. A. Miles, biological secretary of the Royal Society, director of the Lister Institute and professor of experimental pathology in the University of London; Sir Patrick Linstead, foreign secretary of the Royal Society, rector of the Imperial College of Science and Technology; Prof. A. H.

Cottrell, Goldsmiths' professor of metallurgy in the University of Cambridge; Prof. B. Katz, professor of biophysics in University College, London.

### Director of the Bedford Institute of Oceanography, Dartmouth, Nova Scotia: Dr. William L. Ford

DR. WILLIAM L. FORD, chief of personnel at the Canadian Defence Research Board, has been appointed director of the Bedford Institute of Oceanography at Dartmouth, Nova Scotia, and will assume his post on April 1. Formerly Dr. Ford was scientific adviser to the chief of the Naval Staff, and besides being chief of personnel at the Defence Research Board he was a member of the defence research management committee. As director of the Bedford

Institute he succeeds Dr. W. N. English, who recently accepted the position of superintendent of the electronics wing in the Canadian armament research and development establishment at Val Cartier, Quebec. Dr. Ford has carried out research in both the Atlantic and Pacific Oceans. He attended Victoria College and the University of British Columbia, where he obtained his B.A. in 1936 and M.A. in physical chemistry the following year. He continued his postgraduate studies in the same field at Northwestern University in Illinois and obtained his Ph.D. in 1940. Following a four-year period in the Nylon Research Laboratory of the Du Pont Company in Wilmington, Delaware, Dr. Ford directed his attention to oceanographic research in 1944. Until 1948 he carried out research at the Woods Hole Oceanographic Institution. During the atomic experiments at Bikini in 1946, he was a member of the oceanographic team concerned with the drift of radioactive waters at the Bikini site. In 1948 Dr. Ford joined the Naval Research Establishment of the Defence Research Board in Halifax. During 1952-53 he attended the National Defence College in Kingston, and then assumed the position of director of scientific services for the Royal Canadian Navy. He was superintendent of the Pacific Naval Laboratory at Esquimalt from 1955 until 1959, when he returned to Ottawa to assume the position of scientific adviser to the Chief of Naval Staff. In 1963 he was appointed chief of personnel.

#### Chemistry in the University of St. Andrews:

Prof. J. M. Tedder

DR. J. M. TEDDER was recently appointed to the newly created Roscoe chair of chemistry at Queen's College, Dundee, in the University of St. Andrews. He was educated at Dauntsey's School, Wiltshire, and Magdalene College, Cambridge. In 1948 he joined Prof. M. Stacey's group at the University of Birmingham, where he carried out research on organic fluorine compounds. He was appointed University Research Fellow in 1950 and gained his Ph.D. degree a year later. After a further year at Birmingham he continued his studies in the same field with Prof. A. L. Henne at Ohio State University. In 1953 he returned to Britain as an Imperial Chemical Industries Research Fellow at the University of Edinburgh, and in 1955 he was appointed lecturer in chemistry at the University of Sheffield. His research at the University of Sheffield was very productive, and in 1963 he was appointed reader in organic chemistry. Dr. Tedder's early investigations were concerned with trifluoroacetic acid and the use of its anhydride in various organic reactions. His investigations have covered several important areas of organic chemistry and his main contributions have been concerned with the chemistry of diazonium compounds and the examination of gas phase free radical reactions. He pioneered the direct route for the synthesis of diazonium salts and used this method for the preparation of novel acetylenic diazonium salts. He has also been concerned with directive effects in free radical substitution reactions, and recently he has directed his attention towards the factors governing orientation of free radical addition processes.

#### Botany in the University of Liverpool:

Prof. V. H. Heywood

DR. V. H. HEYWOOD, reader in the Department of Botany in the University of Liverpool, has been appointed to the newly established second chair of botany in the University. Dr. Heywood, who is thirty-six years of age, was educated at George Heriot's School, Edinburgh, and the University of Edinburgh, where he graduated B.Sc. with first-class honours in botany in 1949, and was awarded the Class Medal and the MacGillivray Prize in Zoology. He gained a D.Sc. degree in 1964. In 1949 he was awarded a Carnegie research scholarship and a Cross Trust research scholarship at Pembroke College,

Cambridge, where he graduated Ph.D. in 1953. From 1952 until 1955 Dr. Heywood held the post of "Professor agregado" in systematic botany at the Instituto Botánico, Madrid, being appointed special lecturer in experimental taxonomy and technical assessor, Instituto Nacional de Investigaciones Agronomicas, Madrid, in 1955; in the same year he was appointed lecturer in botany in the University of Liverpool. He was promoted to a senior lectureship in 1960 and to a readership in 1963. Dr. Heywood has made a number of expeditions and visits to Spain as well as to Greece, Anatolia and Jugoslavia. He is a member of the Council of the Systematics Association, a member of the Publications Committee of the Botanical Society of the British Isles, secretary of *Flora Europaea* Editorial Committee, and a member of the executive and secretary general (during 1961-63) of the International Organization of Biosystematists.

#### British Museum (Natural History): Appointments

Dr. J. P. Harding

DR. J. P. HARDING has been appointed keeper of the Department of Zoology at the British Museum (Natural History) in succession to Dr. F. C. Fraser, who retired from this post at his own request on November 30 in order to resume his researches on the Cetacea. Dr. Fraser will remain on the staff of the Museum. Dr. Harding, who has been a deputy keeper in the Department of Zoology since 1961, was educated at Torquay Grammar School; University College, Exeter (now University of Exeter); the University of Cincinnati, and King's College, Cambridge. Prior to joining the Museum in 1937, he was for a year an assistant naturalist in the Ministry of Agriculture and Fisheries. Dr. Harding is a carcinologist specializing in the Entomostraca.

Dr. R. H. Hedley

DR. R. H. HEDLEY has been appointed a deputy keeper in the Department of Zoology in succession to Dr. Harding. Dr. Hedley, a graduate of the University of Durham, joined the Museum in 1955 and is a specialist in the biology and cytology of the Foraminifera, with a special interest in the distribution of inter-tidal forms. He held the New Zealand national research fellowship in 1960.

#### Charles Hatchett (1765-1847)

CHARLES HATCHETT, son of a wealthy coach-builder of Long Acre, London, was born two hundred years ago on January 2. Later he was to become noted as the discoverer of what he named 'columbium'—a discovery which he announced in a paper to the Royal Society of London in 1801. He detected it in a mineral (columbite), using part of a specimen collected in New England by Governor John Winthrop the younger (1606-76)—himself a chemist and physician—and sent to Hans Sloane by Winthrop's grandson (the specimen is at present in the British Museum (Natural History)). In 1802 Anders Gustaf Ekeberg (1767-1813) announced the discovery in several minerals of a new metal to be called 'tantalum'. In 1809 William Hyde Wollaston analysed both columbite and tantalite and considered the metals columbium and tantalum to be identical. This opinion, from a chemist of great authority, was generally accepted until 1846, when it was refuted by Heinrich Rose. As tantalum had been named after Tantalus, mythical king of Phrygia (to whom all things were elusive), Rose decided to rename columbium 'niobium' after Niobe, daughter of Tantalus and goddess of tears. Niobium is the name now preferred in Europe and the one which has been accepted by the International Union of Pure and Applied Chemistry; however, the term columbium is still generally accepted in the United States. Hatchett had not in fact isolated the metal, and this was not done until 1864 by C. W. Blomstrand. A versatile chemist, Hatchett worked on, *inter alia*, the nature of lac, magnetic properties of minerals, substances of vegetable origin and (with Caven-

dish) on the durability of the gold coinage, and, in his decade of inspired research from 1796 until 1805, published, through the Royal Society, papers on the analysis of mineral waters, dental enamels and various other topics. Yet, as the historian Thomas Thomson lamented, his "lucrative business weaned him from scientific pursuits"; his withdrawal from chemistry was much regretted by his contemporaries. Apart from his chemistry and coach-building, Hatchett was active in the Literary Club, in which Davy, Wollaston and Blagden also assured representatives among scientists, and also in the Animal Chemistry Club, where Davy, Brodie and Brand discussed work on physiological chemistry.

### The Royal Society of Edinburgh

BESIDES details of its administration, recipients of its awards, meetings and lectures, and election of Fellows, the *Year Book of the Royal Society of Edinburgh* contains information on the contributions which many distinguished past and present Fellows have made to the growth of science and technology (Pp. 136. Edinburgh: Royal Society of Edinburgh, 1964. 20s.; 3.50 dollars). One outstanding Fellow, for example, was Sir William Wallace, who was managing director of Brown Bros. and Co., Ltd., Edinburgh, the marine engineers, from 1916 until 1957. It is reported that "In 1917 he was on board the submarine K. 13 when she sank during trials in the Gareloch, and was instrumental in saving the lives of many on board by blanking off a hydraulic pipe with a two-shilling piece inserted in a pipe coupling". From about the date of William Wallace's appointment as managing director, Brown Bros. and Co., Ltd., has been continually employed by the Admiralty on the development and manufacture of a variety of equipment: in the early 'thirties the company obtained an order to manufacture catapults to an existing design, followed by further development to suit the changing requirements of the Service. The early 'thirties also saw the start of a new venture, when Sir Maurice Denny, of William Denny and Bros., Dumbarton, collaborated with William Wallace in developing the Denny-Brown ship stabilizer: the first was fitted on a cross-channel ship in 1936, followed by a number of similar installations on a large number of H.M. ships during the Second World War, and then, the first of many 'big ship' installations, in the *Chusan* in 1952. Another outstanding record in the *Year Book* is that present developments in management education were foreshadowed by Prof. William Oliver's appointment to the part-time lectureship in organization of industry and commerce at the University of Edinburgh in 1919. During the thirty-three years in which Prof. Oliver was in charge of the Department many important developments occurred. The subject, which was originally confined to the degree of Bachelor of Commerce, was added to the curricula of the degrees of B.Sc. in engineering, technical chemistry and mining, as well as the certificates and diplomas of social study, administrative law and practice and public administration.

### Institute of Navigation

THE annual report of the Council of the Institute of Navigation for 1963-64 covers the year ended June 30, 1964, and records an increase in membership from 2,061 to 2,245 during the year (Pp. 18. London: The Institute of Navigation, 1964). The fourth tripartite conference, organized jointly with the Institut Français de Navigation and the Deutsche Gesellschaft für Ortung und Navigation, was held in Eastbourne in May. As a result of general agreement that immediate measures should be taken to enable ships to navigate through heavily congested areas more efficiently and with more safety, a working group was set up to determine and to propose solutions for the areas in which the problem was most acute. A working group had already been set up dealing with the Dover Straits, and the work of this committee was brought to a satisfactory

conclusion in the year, with 3,513 replies in favour of introducing some form of routing in the Dover Straits in addition to improving the navigational marks and other aids. The report of the working group after consideration by the Maritime Safety Committee in January 1962 is receiving further examination by numerous Governments. The report also refers to the lack of sufficient definite support for Sir John Cass College, London, to start the proposed course in the science and technology of navigation, leading to the award of the College diploma. The course has now been shortened by various arrangements to cover the same subject in 30 weeks instead of 60, but it still appears that many organizations will find it difficult to release employees long enough to take it.

### International Union against Cancer

THE first report of the Director of this Union, which was founded as a voluntary organization in 1935, covers the work of the years 1962-63 (*Activities Report, 1962-63*. Pp. 47; *Manual of the International Union Against Cancer*. Pp. 94. International Union Against Cancer: Geneva, Post Box No. 400, 1964). The president during these very active and productive years was Dr. Delafresnaye, who has now retired and is succeeded by Dr. Alexander Haddow. The Union owes much of its success during these two years to Dr. Harold F. Dorn, who has been its general secretary for 10 years. One of the improvements effected by him was the establishment of a central office in Geneva required for the administration of the Union's fellowship programme instituted in 1960 at the request of the Eleanor Roosevelt Cancer Foundation. The director's report discusses the work of this central office and the other work of the Union; the work of the Commission on Cancer Research and its related Committees and that of the Commission on Cancer Control and the Union's relations with the World Health Organization. The report concludes with a bibliography on various aspects of cancer research, a list of the members of the Union belonging to 67 countries and financial statements for the years 1962 and 1963. The *Manual* describes, in both English and French, the origin of the Union, its present organization and its activities.

### Population Statistics

IN the most recent issue of the Registrar General's *Quarterly Return for England and Wales* a new set of statistics showing seasonally adjusted quarterly figures of birth occurrences and birth rates are given (Quarter ended June 30, 1964. No. 462, second quarter 1964. Pp. 24. London: H.M.S.O., 1964). These figures make it clear that the recent slight decline in the birth rate was temporary; the seasonally adjusted rate of 18.6 for the second quarter is the highest since 1947 and would indicate that there may be approximately 870,000 births in 1964, compared with 856,000 in 1963. The natural increase for the first half of 1964 was approximately 165,000. Infant and neo-natal mortality have continued to fall. The expectation of life shown by the abridged life table, which is normally published in the second quarterly return, is very slightly lower than twelve months ago, mainly as a result of the higher death rates in the exceptionally severe winter of 1963.

At the same time as this *Return* was published, the *Population Bulletin* of the Population Reference Bureau Inc., a private American organization, has devoted its September issue to the new pattern in American fertility (Vol. 20, No. 5, *New Patterns in U.S. Fertility*. Pp. 113-140. Washington, D.C.: Population Reference Bureau, Inc., 1964. 50 cents). In the United States, too, fertility is rising rapidly, and the recent slight decline in births is probably due only to a shift in the age distribution of women of reproductive age. As the larger birth cohorts of the 1950's begin childbearing themselves, the number of births is likely to go up sharply. The *Bulletin* article deals

with some of the social factors which influence fertility, and directs attention to the growing importance of the gap in the fertility between different religious groups, which is accompanied by a narrowing of income, educational and occupational differentials. It seems clear that relative affluence in the two richest countries of the world has led to a resurgence in population growth. Unfortunately, much less research on the subject has taken place in Britain than in the United States, and a detailed assessment of fertility changes, such as is provided by the survey in the *Population Bulletin*, is not possible for Britain at the moment.

### Mental Health in Britain

THE recent *Supplement on Mental Health* to the Registrar General's *Statistical Review* for 1960 is the last of a series of reports on this subject, which have appeared since 1949, to be issued by the General Register Office (Pp. vii + 191. London: H.M.S.O., 1964. 15s. net); future reports will be issued from the Ministry of Health. The report contains the usual data on admissions, discharges and lengths of stay in mental and mental-deficiency hospitals, classified by sex, age and diagnosis, which one has come to expect in this publication. There are two principal innovations. Admissions and discharges by age and sex are given for a sample of 20 individual mental hospitals, selected so as to give adequate coverage of different size groups, as size is considered to have an influence on the movement of patients. In the second place, there is a decrement table, showing the number and percentage of patients admitted in 1959 who remained in hospital, died or were discharged at various periods up to one year of their date of admission. These data are given for each sex by three age groups, and it is hoped in subsequent years to break these down further by marital status and diagnostic group.

### Day Centres for Children

THE series published by the World Health Organization entitled *Public Health Papers* is intended as a medium for the publication of occasional papers prepared as contributions to the study of particular health problems. No. 24 of the series is entitled *Care of Children in Day Centres* (Pp. 189. Geneva: World Health Organization; London: H.M.S.O., 1964. 7 Sw. francs; 12s.; 2.25 dollars). The publication consists of ten chapters by eight authors on various aspects of the subject and includes a contribution from the International Labour Office and articles on day centres in Poland and Paris. It should be useful to everyone who is concerned with the care of children.

### South African National Parks

*Koedoe*, the journal for scientific research in the National Parks of the Republic of South Africa, No. 7 (1964), contains fifteen papers, mostly on zoological subjects, both vertebrate and invertebrate, with two each on botany and geohydrology. The Parks present a magnificent opportunity for research, and the National Parks Board of Trustees is to be congratulated on publishing this valuable journal incorporating the results of work carried out under its auspices. The present issue contains several systematic and faunistic papers, and an interesting ecological study of the plant communities of the sandveld flora of the northern section of the Kruger National Park by H. P. van der Schijff. F. C. Eloff contributes new observations on the predatory habits of lions and hyenas, and an unusual paper by K. Babich gives an account of animal behaviour with respect to tourists in the Kruger National Park.

### Precise Measurement in Engineering

A 16-MM FILM entitled "Precise Measurement in Engineering" has been prepared by Film Workshop, Ltd., for the Department of Scientific and Industrial

Research through the agency of the Central Office of Information. Modern mass-production techniques demand accuracy in the design and manufacture of components in order that randomly selected parts may be interchangeable. The film examines the significance of precision measurement to the engineering designer and to the industry as a whole. In dealing with present industrial techniques of inspection, it shows how factory floor gauges are checked against factory standards which are, in turn, checked against standards maintained by the National Physical Laboratory. The film, which runs for 28 min., shows the principles and practice of precision measurement, and will be of special interest to production engineers, designers and quality control inspectors. Engineering students in particular should find the animated sequence on interferometry most valuable. Applications for loan should be addressed to the Central Film Library, Government Building, Bromyard Avenue, Acton, London, W.3, the Scottish Central Film Library, 16-17 Woodside Terrace, Charing Cross, Glasgow, C.3, or the Central Film Library of Wales, 42 Park Place, Cardiff.

### Steam Curing of Concrete at Atmospheric Pressure

IN the production of precast concrete products, steam curing is a method increasingly used for the purpose of accelerating the hydration of the cement. Some advantages of this process are that it permits earlier removal of the product from moulds and pallets and allows earlier transfer of prestress in the case of pretensioned prestressed units; the use of steam keeps the concrete moist, at the same time raising its temperature. Steam curing, otherwise known as 'damp heat' or 'low-pressure steam curing', is practicable up to a maximum temperature of 100° C at atmospheric pressure; at higher temperatures pressure must be raised appropriately to keep the steam saturated. This subject is discussed in some detail in a paper by P. W. Keene entitled "Concrete Cured in Steam at Atmospheric Pressure" (*R/Bou* 112, National Building Research Institute, South African Council for Scientific and Industrial Research, Pretoria. Reprinted from *Prestress*, 13; December 1963). Mr. Keene finds that "Maximum early strength is obtained by delaying the application of steam until a certain time after casting, the length of this period depending on the total period available for steam curing. Under optimum conditions it is possible to obtain within one day at least 50 per cent of the compressive strength that would be obtained at 28 days by curing at normal temperature". Of the other characteristics involved, tensile strength and modulus of elasticity at early ages are increased, but to a lesser extent than the compressive strength; there is a reduction in initial drying shrinkage and creep; permeability is increased, but there is a tendency for frost resistance to be reduced; bond with plain steel reinforcement is reduced; ultimate load of pretensioned prestressed units may, in certain circumstances, be reduced; and corrosion of steel reinforcement is increased if calcium chloride is present. The application of steam curing is restricted to products made with certain types of cement; some cements lose strength at high temperature, for example, high alumina cement products above 25° C, supersulphated cement above 40° C. This paper is an excellent summary of present-day knowledge of the effects on concrete of steam curing at atmospheric pressure.

### Gemstones in New South Wales

THE Geological Survey of New South Wales (Department of Mines) is in the process of issuing a Summary Report Series covering the mineral industry of that State, to replace the valued *Mineral Industry of New South Wales* (1928) now long out of print. Of the 45 reports projected in this new series, many of which are apparently not yet published, No. 18 on *Gemstones* (compiled by G. Rose. Pp. 60. Sydney: Government Printer,

1960. 4s.) is of particular interest to the general reader of the subject. The minerals dealt with, in the order listed in this report, are: opal; diamond; sapphire and ruby; emerald and beryl; topaz; turquoise; garnet; spinel; titanite; zircon and quartz. In the introduction it is noted that: "New South Wales opal is world famous and has constituted 88.6 per cent of the value of all gemstones produced in this State. This must give opal the rank of our premier gem" (see also *Nature*, 204, 1151; 1964). To be used as gems, the quality of all these minerals must be of the highest standards; "... unfortunately the Australian diamonds and sapphires are generally poor when compared with overseas material". This does not detract from their industrial value for other purposes, however. The general treatment of each of the other minerals described follows an orderly scheme of information on composition and properties, varieties (where applicable), history and mode of occurrence, and occurrences in New South Wales. In a short section under the heading "Miscellaneous", it is recorded that: "Several other minerals occurring in New South Wales have been used for semi-precious stones. Alunite, azurite, chlorite, fluorite, jet, malachite, prehnite and rhodonite may be included in this group". This report concludes with a useful list of references, chiefly to literature concerning New South Wales; it also includes a small-scale folding map of the State depicting, in colour, areas and 'spot' localities where opal, diamond and sapphire are separately exploited.

### Phosphate Deposits of the South-West Pacific

In 1955 a programme of exploration for island phosphate deposits, to supplement the dwindling reserves of Ocean, Nauru, and Christmas Islands, was agreed on by the Australian and New Zealand Governments, and a noteworthy report resulting from these investigations has recently been published (*A Survey of Phosphate Deposits in the South-West Pacific and Australian Waters*. By W. C. White and O. N. Nairn. 173 pp. *Bulletin* No. 69, Bureau of Mineral Resources, Geology and Geophysics, Commonwealth of Australia, 1964). The Ocean Island phosphates discovered can be grouped into the four classes of (1) avian guano deposits of modern and recent date; (2) phosphatized sands (phosphatic guano) on cays and atolls, resulting from the decomposition of guano under warm arid conditions and subsequent metasomatic replacement of underlying carbonate sands; (3) ferruginous-aluminous phosphates, often oolitic, on elevated limestone islands, formed under lagoonal conditions from an admixture of phosphatized sediments and guano residues with transported terra rossa clay derived from limestone weathering; (4) high-grade phosphate rock on flat-topped oceanic islands, occurring between pinnacles of dolomite, with a more complex history. Of the new finds, those of significant size are restricted to Bellona Island in the British Solomon Islands Protectorate, but their potentialities do not materially augment the resources previously known which, at the present rate of production, will be exhausted in about thirty years. Under ideal conditions where arid islands are adjacent to regions with an upsurge from depth of cold, phosphatic, oceanic water, providing the nutrient for extensive marine life on which birds subsist, the rate of deposition of modern avian guano deposits can be as high as 8-10 cm annually. In addition to valuable discussions on the genesis of these phosphates, this well-written memoir provides a review of geological and topographical conditions in the Solomons, the islands off Papua and New Guinea, the Gilbert and Ellice Islands, Ocean Island and Nauru, Christmas Island, the Fiji archipelago, and the islands of the Northern Territory of Australia.

### International Conference on Thermal Analysis

THERMO-ANALYTICAL techniques, and particularly thermogravimetry and differential thermal analysis, are

becoming increasingly common in research and in industry, and are now being applied in fields quite distinct from those for which they were developed. The techniques, too, have developed differently in various countries, depending on the outlook of the research workers and the apparatus available. Consequently, it has been considered by many interested parties that a broadly based international interdisciplinary convention should be organized at which problems, questions of interpretation and results can be discussed. Moves in this direction have now been made by a small international committee (consisting of Prof. R. Barta, Czechoslovakia, Prof. L. G. Berg, U.S.S.R., Prof. L. Erdey, Hungary, Dr. R. C. Mackenzie and Dr. J. P. Redfern, Great Britain, Dr. C. B. Murphy, United States, and Prof. T. Sudo, Japan), which is at present organizing the "First International Conference on Thermal Analysis", to be held in Aberdeen, Scotland, during September 6-9, 1965. The main theme of the conference will be "Thermal Techniques and their Applicability" and circulars giving details are now being distributed. These, together with any further information, can be obtained from Dr. R. C. Mackenzie, the Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen, Scotland, or from any other member of the committee.

### The Chemical Institute of Canada

DR. ROGER M. BUTLER of Sarnia, Ontario, has been elected chairman of the Chemical Engineering Division of the Chemical Institute of Canada. Dr. Butler received his degrees from the Imperial College of Science and Technology, London. From 1951 until 1954 he was assistant professor of chemical engineering at Queen's University, Kingston, Ont. Since 1954 he has been in Sarnia with the research department of Imperial Oil on process development and more recently as senior research chemist for new projects. The Chemical Engineering Division is the engineering arm of the Chemical Institute of Canada, Canada's national organization of chemists and chemical engineers. Dr. Butler succeeds Dr. W. J. M. Douglas of McGill University, Montreal. Other new officers elected were: *Vice-chairman*, Dr. D. B. Robinson, University of Alberta, Edmonton; *Secretary-Treasurer*, Dr. N. E. Cooke, Canadian Industries, Ltd., Montreal.

### Announcements

MR. FREDERICK D. MCCARTHY, formerly curator of anthropology, Australian Museum, Sydney, has been appointed principal of the Australian Institute of Aboriginal Studies, Canberra, and took up his duties on November 16. The Institute was set up by the Commonwealth Government of Australia to record information about the Australian Aborigines and their culture by promoting research through universities, museums and individual field workers.

THE twelfth annual conference of the Western Spectroscopy Association will be held in Asilomar, California, during February 4-5. The programme will include sessions on: spectroscopy with lasers; molecular vibrations; molecular spectroscopy of planets and stars; non-radiative energy transfer. Further information can be obtained from M. W. Windsor, Quantum Chemistry Department, TRW Space Technology Laboratories, One Space Park, Redondo Beach, California.

AN international symposium on "The Impact of Mendelism on Agriculture, Biology and Medicine", organized by the Indian Society of Genetics and Plant Breeding, will be held at the Indian Agricultural Research Institute, New Delhi, during February 15-20, to commemorate the Silver Jubilee year of the Society and the centenary year of the publication of Mendel's classic paper. Further information can be obtained from Dr. A. T. Natarajan, Division of Botany, Indian Agricultural Research Institute, New Delhi 12.

## EDUCATION FOR BUSINESS AND MANAGEMENT

THE debate on education for business and management which Lord Alport opened in the House of Lords on November 18, in which Lord Snow made a distinguished maiden speech as Parliamentary Secretary to the Ministry of Technology, greatly transcended any previous debate in Parliament this session, and was, moreover, free from the pettiness which has marred most of those in the House of Commons so far. Lord Snow did not attempt to claim all the credit for advances in management education for the Government, but, apart from his tributes to the work of Lord Franks, Lord Robbins, Lord Nelson of Stafford and Lord Normanbrook, for example, generously acknowledged the foundation laid by the previous Government and stressed the need for close co-operation between Government, industry and the academic world, without concern as to who received the credit. After mentioning the support which Lord Nelson had secured from industry for the two new business schools, Lord Snow stressed the imperative necessity for us to use with intelligence and imagination every scientific resource we had and he put management studies among the twelve or twenty most important tasks we had to tackle for survival within the next two or three years. Besides the two new institutions there were courses at various universities or colleges of advanced technology leading to a postgraduate degree, courses at regional colleges of technology leading to diploma in management studies, and finally a large amount of management education within firms themselves. Lord Snow declined to say that any one method was more important than the others: all would be needed. Probably less than 3 per cent of managers required no training, and apart from perhaps 20 or 30 per cent who would not be improved, the rest would be greatly improved by training. The next problem was to find the teachers, and here much more part-time help from industry was essential. Industry, too, had to make appropriate dispositions to utilize those who had been trained; finally, there was the vital problem of effective selection.

Most of these points had been put in questions by Lord Alport, but Lord Snow did not reply to his question about the need for increased research facilities. This aspect was specially emphasized by Lord Bowden later in the debate, who thought it was even more important that industry should co-operate in this field than that it should co-operate in teaching. Unless research workers from a business school could go into industry and investigate industrial problems on the shop floor the subject would never advance. Lord Bowden illustrated his point by referring to two investigations carried out from the Manchester College of Science and Technology within the past two or three years. The first, with the active support of the Ministry of Health and the collaboration of the hospitals concerned, was into a group of hospitals of similar size, appearance and scope and revealed remark-

able differences in the skill with which hospitals could retain and train nursing staff and in the time taken for a patient to recover from similar conventional operations. Another survey, of the attitudes of workpeople to general problems of innovation and change, indicated variations between factories which greatly exceeded those within a factory, and the differences in attitude of mind were strongly correlated with the communications system within the factory.

Lord Bowden maintained that such problems of the pathology of a hospital or factory were much more easily handled by investigators with the impartial reputation that a business school or a university could ensure and he believed that in this way such institutions could make an important contribution in efficiency.

Earlier in the debate, the Bishop of Chichester, supported by Lord Kilmuir, had emphasized the personal aspects and particularly the importance of people, alike in research and in training for management: there was a moral aspect which could not be disregarded. Lord Plowden put his emphasis on co-operation between industry, the universities and the Government, while Lord Nelson of Stafford stressed the importance of making the most of existing experience, of securing an adequate supply of trained teachers, of effective co-ordination between the various types of courses, and of the Government ensuring that adequate grants were available for the students who came forward. Lord Chorley, who referred to the Beveridge Experimental School of Economics, thought the failure of the earlier schemes was worth studying and that the pioneer work of Lord Beveridge was not sufficiently appreciated. Lord Geddes of Epsom, commenting on the increasing need for managers to be scientifically minded, raised an important point about the use of scientists as administrators: it could be a serious situation if scientists could not easily enter the managerial class if they were competent. Lord Aberdare stressed the need for first-class and imaginative teachers in the business schools and supported Lord Bowden's remarks about constant interchange between the academic and the industrial world. Lord Shackleton, in concluding the debate for the Government, was also studiously fair in acknowledging what had already been done under the previous Government, but was unable to offer at this stage any firm assurance about grants for students, and while he undertook that the Government would continue to co-operate he could say little on co-ordination, and the responsibility for management education, he said, would lie with the Secretary of State for Education and Science, and, for non-university courses in Scotland, with the Secretary of State for Scotland. Although the Ministry of Technology, the Board of Trade, and the Ministry of Labour might also be concerned, management education should properly grow out of the educational system.

## SCIENTIFIC AND INDUSTRIAL RESEARCH IN NEW ZEALAND

THE annual report of the Department of Scientific and Industrial Research, New Zealand, for the year ended March 31, 1964 (Pp. 87. Wellington: Government Printer, 1964. 3s.), records a gross expenditure of £2,607,112, or £2,538,794 net, of which about 42 per cent is estimated to be on agricultural research and 27 per cent on industrial research, including grants totalling £200,577 to incorporated research associations. Rather less than 10 per cent of the total expenditure is for scientific

services, mainly for other Government Departments and for industry. The major items of expenditure were £279,253 on the Dominion Physical Laboratory, £264,265 on the Dominion Laboratory, £165,908 on the Geophysics Division, £138,061 on the Soil Bureau, £132,616 on the Geological Survey, £122,414 on the Grasslands Division, £116,471 on the Antarctic Division, £111,524 on the Plant Diseases Division, and £94,458 on the Oceanographic Institute. The staff increased during the year from 1,229

to 1,287, the latter figure including 472 professional, 552 technical, 182 clerical and 81 others.

The Director-General, directing attention to the applied research which constitutes most of the Department's work, notes that the experimental measures for controlling yellow dwarf virus disease of barley are estimated to have saved £112,000 in one season. He also stresses the importance of the fundamental research on which this applied research is based, instancing the discoveries of the Fruit Research Division relating to plant cell division and the advances in understanding of wood shrinkage and aurora made by the Dominion Physical Laboratory. In a geochemical laboratory of the Geological Survey and University of Otago investigations at high temperatures and pressures have shown that greywackes and argillites constituting many New Zealand mountain ranges lose their chlorite minerals and begin to grow other platy minerals like mica when heated below their melting point at pressures up to 1,000 atmospheres, and the growth of the platy minerals can be oriented in one plane to give schistosity similar to that in large areas of Otago rocks. Laboratory research has also shown that temperature is the most important factor in the conversion of lignite into bituminous coal.

Sheep grazing trials in the Manawatu on New Zealand short-rotation and on Arika and Italian ryegrass indicate that cellulose content is an important controlling factor in the nutritive quality of ryegrass. The Grasslands Division has demonstrated the practicability of high-stocking rates on steep hill country at Te Awa and has found that heavier stocking rates may limit the useful life of ewes by increasing the wear on the sheep's teeth. Movements of mineral constituents through the soil have been demonstrated by the use of radioisotopes, and recent work at the Soil Bureau has shown that severe iron deficiency in *Crotalaria*, a tropical legume used as a green manure crop, can be corrected by use of iron chelate, which is stable under alkaline conditions. Rabbit population investigations have emphasized the importance of natural predators of rabbits in control in the wild, and

field experiments have confirmed the wide existence of grass-grub populations tolerant to DDT. A new crown-rust resistant strain of 'Onward' oat has been bred by the Crop Research Division and released as 'Onward (1963)', and the Division is also testing potato hybrids for processing for export. The Fruit Research Division has now succeeded in isolating from immature sweet corn seeds a natural cell-division stimulant, or kinin, which has been named 'Zeatin', and its synthesis is now being attempted.

Systematic astrolabe observations were recommenced in January 1964, and the Dominion Physical Laboratory has shown that very low-frequency signals travelling over long distances can sometimes suffer such severe phase distortion as to render them useless for navigational purposes. A small-scale process for steel castings has been further simplified by using a charge composed almost entirely of steel scrap and adding silica and manganese as ferro-alloys to produce the heat of reaction. The economics of the process are satisfactory and it now has possibilities for the average New Zealand foundry.

The main programme of geothermal investigation at Ngawha has been completed, but prospects of useful resources within economic depths do not appear hopeful. In investigations of the optimum sulphate content of cements a method has been developed for determining the degree of dehydration of gypsum, and the Wheat Research Institute, from theoretical investigations of the loss of steam from bakers' ovens and the development of an instrument for rapidly measuring the concentration of steam in the oven, has devised important designs for bakers' ovens and a number of travelling ovens have been built to this design. Reports from the various branches are included in the report, to which lists of publications during the year are appended. The sixth annual report of the Ross Dependency Research Committee is also appended, as well as brief reports on grant-aided research in the Cawthron Institute, Lincoln College, Massey University College of Manawatu, and the University of Canterbury.

## SCIENTIFIC POLICY IN BELGIUM

**THE** *Inventaire du Potentiel Scientifique de la Belgique* — *Année 1961*, issued by the National Council for Scientific Policy (Pp. 303. Brussels, 1964) is in three parts. The first sets forth the reasons for the survey, its principal characteristics and the methods used. The second, which occupies roughly one-half of the report, contains the statistical information and appendixes, while a third part, occupying about one-third of the whole, lists the units participating in the survey. The survey estimates the number of effective full-time personnel in 1961 as 22,504 engaged in 1,644 scientific units, and of these 6,703 were of university status, 2,451 held higher technical diplomas and 13,350 were technicians, craftsmen and others. Excluding those in the sector of teaching, inter-university centres and learned societies, the expenditure of these units was about 4,312.9 million francs. Of these 1,644 units, 1,284 were concerned with the exact sciences (628 with technology) and 180 with the social sciences, and another 180 with the other research sciences; the numbers of those with a university degree thus occupied are 5,433, 821 and 448, respectively. Again, in 81.5 per cent of those in the field of education, 71.6 per cent of those in the public sector, 55.7 per cent of those in private industry, 61.4 per cent of industrial or agricultural research associations, 50 per cent of other private establishments and in all the inter-university centres research is an important activity, the percentage of university graduates engaged in such activities being estimated at 85.5, 73.9, 86.6, 71, 56.3 and 100, respectively.

The four universities employed 80 per cent of the scientific units and 88 per cent of the personnel with university qualifications in the educational sector; 56 per cent of the latter was in the faculties of science and medicine. Ministerial departments included 64 per cent of the scientific units and 59 per cent of university graduates in the public sector; 45 per cent of the latter being employed in the Ministries of Education, Agriculture and Defence. Although private enterprise and the industrial and agricultural research associations only include 16 per cent of the scientific units, they include 58 per cent of university graduates engaged in research in this sector, 17 per cent of these being in the research associations. Firms with more than 1,000 employees with research departments numbered only 10 per cent of firms engaged in such activities and employed 49 per cent of the university graduates in this sector.

Nearly half the scientific units and more than half the university graduates engaged in such activities are employed in the province of Brabant, those of Liège and East Flanders coming next with 15 per cent each, mainly in the educational sector in East Flanders. In the exact sciences, mathematics accounts for 54 per cent of the units and 62 per cent of the personnel. Those engaged in technology employed 20 per cent of university graduates engaged in scientific work in industry, but in the educational field only 14 per cent of the scientific units and 14 per cent of university graduates were concerned with technology. In the exact sciences 25.9 per

cent of units and 33.7 per cent of personnel were engaged exclusively or mainly in fundamental research, compared with 62.1 per cent and 54.1 per cent, respectively, for applied research.

Nearly 10 per cent of the scientific units employed no persons with university qualifications and nearly 90 per cent of the units employed not more than 10, while about a quarter had no technicians or trained auxiliaries. Some 60 per cent employed no one with technical diplomas and nearly half the remainder employed only one such person. In the educational sector, 24 units employed some 15 per cent of the university graduates, mainly in the

faculties of science and medicine, while in the public sector 13 per cent were employed in 3 per cent of the units in this sector, especially at the Centre for the Study of Nuclear Energy. Excluding the educational sector in the exact sciences, about half the units spent less than 1 million francs on research in 1961, and half these not more than 700,000 francs. In the public sector, including research associations, half the units spent not more than 3 to 4 million francs, while ten private enterprises, responsible for 60 per cent of the expenditure on such activities by private enterprise, spent more than 50 million francs and 5 of those 100 million francs.

## REGIONAL ADMINISTRATION IN FRANCE

**A** PAMPHLET, *The French Administrative Reform*, issued by the Press and Information Service of the French Embassy, describes the structures of the Departments, of the Paris region, and of the other Regions as modernized by the decrees of March 14, 1964 (Pp. 30. London: Ambassade de France, Service de Presse et d'Information, 1964). The reforms, which will be implemented over a period extending to at least 1965, are based on the results of experiments conducted during two years in five test departments and in the pilot regions of Upper Normandy and Burgundy. The basic principle consists in making the Prefect once more solely responsible for the State service; the sole representative of the Government in the Department, he is the sole co-ordinator of public activities, with the exception of the military services, judicial services, assessment and collection of taxes, payment of public expenses, valuation of national property, factory inspection and supervision of the application of the social loans in agriculture. To ensure that the Prefect is fully informed of all important aspects of life in his Department, a central correspondence service will provide photographic copies of incoming letters, while copies of outgoing letters will also be submitted. Delegation of power is provided for certain highly technical services but delegation of signature allows more freedom and flexibility to heads of services.

A similar principle has been applied to the regions but only to external services concerned with economic matters, public investment and equipment, those which manage Government stocks or participate in programmes

involving national public funds. Such State services in the regions will be placed directly under the Prefect of the Region and cease to be directly under the Paris ministries. The Prefect will accordingly now have a role of initiation and decision in the economic field and a simple function of co-ordination in the administrative field. He will be assisted by an enlarged inter-departmental administrative conference and by a new commission on regional economic development. The new commission will be consulted when the Government prepares future development plans, after the draft has been submitted to Parliament and again after the final planning project has been discussed by Parliament and the operative sections relating to each region have been defined.

This regional reform does not apply to the Paris region, the administrative districts of which are being subdivided to give smaller units while a single assembly will replace the General Council and the Municipal Council, retaining on the whole the powers of the present Municipal Council and assuming those possessed by the General Council of the Seine. The suburbs are to be divided into Departments of normal status, while the pilot prefectures will permit construction of national administrative cities in each chief town. Provision is also made for a system of administrative and economic co-ordination, including a regional assembly or council, the composition of which is not yet fixed. Additional financial resources will be provided and it is anticipated that the new organization should be functioning smoothly by 1968.

## THE BUILDING RESEARCH STATION

**A**T its headquarters in Bucknalls Lane, Garston, Watford, Herts., the Building Research Station (Department of Scientific and Industrial Research) had its 'Open Days, 1964' during September 22-25, when members of the public, including Press representatives, were accorded an unrivalled opportunity of seeing something of the inside workings of this long-established and important organization. Displays and hourly full-scale demonstrations illustrating some of the more important activities of the Station and many items of present-day research were made available to the visitors. In the department concerned with building operations and economics, the theme is research into the efficiency and economy of building operations, development of new techniques, examination of methods of management and organization, and factors influencing costs. Mechanical engineering deals with research applied to production and handling of building components on site and in the factory, and investigations in the engineering services requisite to completed buildings. Environmental physics is concerned both

with factors controlling conditions in buildings and with the subjective reactions of the occupants to these conditions. The section devoted to user requirements and design deals with building design and occupants' requirements in relation to housing and to some special building types. Research in the materials department ranges from the constitution and properties of building materials to investigation of their behaviour in use, including laboratory-scale tests to pilot plant trials. Structural engineering is concerned fundamentally with loadings, with the behaviour both of components and of full-scale and model structures, and with the engineering properties of building materials.

The soil mechanics department was the first to be set up in Britain. It has done pioneer work on the engineering properties of soils and their relationship to the structural behaviour of foundations, tunnels, retaining walls and earth dams. A section devoted to mathematics provides a service for the rest of the Station, and present-day work, reflecting projects in three other departments, includes the

theoretical basis for modular design, the theory of micro-wave techniques for moisture measurement, and the theory of sound transmission through lightweight partitions. Building practice is concerned with external contracts, technical enquiries, co-ordination of work on British Standards and Codes of Practice, building legislation, etc. The tropical building section is concerned with special problems of housing, building and planning in tropical and subtropical countries. Apart from these instructive demonstrations, facilities were available for providing technical information, in the form of leaflets giving background information and details of the researches involved in many of the exhibits; the technical enquiry service was in operation, dealing with questions

on the technical aspects of building construction; the Station library was open to visitors and various official publications of the Station were displayed. In this latter connexion an important publication has since appeared entitled *Developments in Roofing* (Building Research Station Digest 51 (Second Series), October 1964; pp. 6, 4d.). This Digest discusses the properties, construction and laying of roof decks and the weatherproof coverings applied to obtain satisfactory performance. It also deals briefly with the properties of some new roofing materials. This is an excellent and up-to-date summary of both conventional and unconventional roofing practices (excluding tiling) and a copy should be available to architects and all others concerned with modern building construction.

## STRUCTURE AND INTEGRATIVE FUNCTIONS OF NERVOUS SYSTEMS

**D**URING the Southampton meeting of the British Association, Section D (Zoology) discussed some recent progress in our knowledge of nervous systems, particularly the relationship between structure and function. The first two speakers were concerned with invertebrate animals, many of which continue to provide preparations and information which is of value in furthering our understanding of basic nervous mechanisms. The second two speakers presented data from two fields of study which have greatly advanced our knowledge of the mammalian brain during recent years.

Dr. E. A. Robson (Department of Zoology, Cambridge) began appropriately with a quotation from Sherrington's classic *The Integrative Action of the Nervous System*, in which he said "in the multicellular animal . . . it is nervous action which *par excellence* integrates it, welds it together from its components, and constitutes it from a mere collection of organs an animal individual. This integrative action in virtue of which the nervous system unifies from separate organs an animal possessing solidarity, an individual, is the problem before us . . .". In discussing coelenterate nerve-nets, Dr. Robson pointed out that these animals are without a central nervous system and yet show a remarkable degree of integration in their behaviour. Histological studies of the nervous systems of jelly fish and sea anemones by Schäfer and the Hertwigs in 1878 had shown the existence of neurones as separate units. Their work, in fact, provided early support for the neurone theory, which was only established later from data on the vertebrate nervous system. Dr. Robson went on to review the classical work of Pantin and his co-workers which, by means of electrical stimulation and mechanical recording techniques, had made it possible to interpret the behaviour of coelenterates in terms of the properties of neuromuscular and interneural facilitation. Thus it had provided valuable physiological support for the view that the nerve net is synaptic. The distinction was made between through-conducting systems responsible for the protective response of a sea anemone and the swimming beat of a medusa, and the more localized responses which are co-ordinated by a net in which the number of synapses to be crossed appears to be greater.

In addition to these reflex responses, coelenterate behaviour is also characterized by inherent activity, first studied in detail by Batham and Pantin using the sea anemone *Metridium*. This animal shows rhythmic expansion and shortening which are usually synchronized with dawn and dusk, but may persist in total darkness for at least three weeks. The interaction of this and other autonomous phases of activity with responses to environmental stimuli can produce impressive sequences of behaviour—well illustrated by the observations of Ross on the transference of *Calliactis* from one whelk shell to another.

More recent advances in our knowledge of the coelenterate nervous system have resulted from the application of electrical recording methods to these animals. This was first achieved by Horridge, who recorded a nerve impulse in the through-conducting system of the jellyfish, *Aurelia*. More recent work has shown that a variety of electrical phenomena can be recorded using micro-electrode techniques. With electrodes in the foot of *Hydra*, Passano and McCullough recorded a constant background of potentials which arose from this region. They could be excited by light and were possibly endogenous to the endodermal nerve net. They also observed bursts of impulses which were associated with spontaneous longitudinal contractions. These arose from the hypostome and were initially inhibited by light and possibly occur in the endodermal nerve net. Other potentials were associated with attachment of the tentacles during locomotion and other tentacular movements. Clearly there is considerable electrical activity in the nervous system of *Hydra* and exactly what mechanisms are involved is only now being investigated. It suggests that the behaviour of *Hydra* is controlled by a hierarchy of pacemakers which are in turn influenced by sensory stimuli. Josephson has found a similar picture in the marine hydroid *Tubularia*, where rhythmical potentials often not directly related to visible behaviour are also observed. The application of these methods has revealed new physiological problems, since, for example, it appears that there are sometimes more than two separate conducting systems, although only two separate nerve nets, ectodermal and endodermal, have been recognized structurally. Dr. Robson suggested that other structures such as muscle fields may have a role as conducting systems.

It seems probable that, as with other invertebrates, the ability to 'tune in' to the nervous activity will give us far more detailed information about the integrative mechanisms where previously our information was based largely on the overt behaviour and responses of the animal. The application of similar techniques has very recently led to the recording of the electrical signs of nervous action in the remaining major group of animals in which it had not been achieved—the Echinoderms, which also rely a great deal upon a nerve net.

Dr. G. M. Hughes (Department of Zoology, Cambridge) explained that the title of his talk, "Electrophysiological Anatomy of Invertebrate Nervous Systems", had been chosen to emphasize the way electrophysiological techniques developed, for the investigation of detailed mechanisms of nervous function is of value in establishing both gross and micro-anatomical features of nervous organization. Thus, in the crayfish they have shown that the areas innervated by a given segmental nerve are not confined to a single segment. Furthermore, the segmental pattern of the sensory innervation of the abdomen is out of phase with the segmentation of the ganglia supplied by the

sensory nerves. Electrophysiological studies are of particular value not only in establishing the anatomy of the system but also because they give information about the functional connexions between neurones. In experiments on the abdominal cord of the dragonfly larva and crayfish, use has been made of the separation of synaptic regions in different ganglia by splitting the connectives between ganglia and so recording the effect of inputs from different segments. Several types of sensory-interneurone connexion have been established; in a common one a given interneurone makes connexions with homologous sensory inputs entering several ganglia. Impulses initiated in these separate synaptic regions will collide following simultaneous stimulation of inputs to different ganglia. Such interneurons produce different patterns of impulses depending on the particular way the sensory field is stimulated.

The sea hare, *Aplysia*, has provided many useful neurophysiological preparations, one of which has recently been found during electrophysiological studies of the anatomy of the two largest cells on each side of the nervous system. One of these cells (LGC) is in the left pleural ganglion and the other (RGC) on the right side of the abdominal ganglia. These two cells send axonal branches into many of the nerves which innervate the foot and parapodia.

Stimulation of any of these nerves is followed by the recording of an antidromic spike in the cell soma and, conversely, an impulse may be recorded in the axon when the soma is stimulated. It has recently been shown that both cells innervate not only ipsilateral regions but also send branches to the contralateral nerves. Direct stimulation of the RGC in whole animal preparations does not lead to any muscular contraction. They are probably homologous cells whose different positions in the CNS result from the processes of torsion and detorsion during development. Functionally, a direct synaptic connexion between the two cells has been established from the RGC to the LGC but not vice versa, and both cells have several common interneurons. Both giant cells show a remarkable degree of habituation in their response to synaptic inputs, there being a marked fall in the response between the first and second stimuli.

Other *Aplysia* neurones have shown that conduction between two axonal branches is not always equally possible in both directions. This provides a possible mechanism whereby only a part of the total output from a given neurone might be excited by a given input. In this way a single neurone could sub-serve the functions usually ascribed to several neurones. Some recent observations have also suggested that similar mechanisms may be involved in the separate function of portions of neurones in arthropod central nervous systems. Such devices, together with variations in synaptic properties, will be of great value as integrative mechanisms. They also suggest how animals with relatively small numbers of neurones may be able to accomplish more complicated feats of integration than might have been supposed had each neurone functioned in an all-or-none way and as a single unit according to the neurone doctrine.

In concluding the discussion of the first half of the symposium, the President of the Association (Lord Brain) emphasized how, despite many advances in the techniques being used for these investigations, the experimental methods were based on those established by the classical studies of Sherrington.

Dr. J. de C. Downer (Departments of Psychology and Anatomy, University College, London) prefaced his paper on "The Role of Brain Commissures in Interhemispheric Transfer of Training" with a point of view which is generally accepted by students of brain and behaviour, namely, that the ability of an animal to learn depends on the structure and organization of the brain. Hence an obvious technique is to remove specific regions of the brain and to test the ability of the animal to retain some previously learned solution and, if lost, its ability to

re-learn. Results of such investigations have proved extremely difficult to interpret but have demonstrated quite clearly that the vertebrate brain, as with some invertebrate nervous systems, is characterized by the ability of one part to take over the function of another following its ablation. From some classical experiments, Lashley concluded that sub-cortical learning does not occur when the cortex is present and that it can only take place following cortical damage.

Dr. Downer went on to describe experiments in which he had made use of the split brain preparation introduced to this type of study by Sperry and Myers. Their experiments clearly showed that when the visual input is restricted to one-half of the brain (by cutting the crossed optic nerve fibres and occluding one eye) visual information normally crosses from the half receiving the input to the other half via the large commissures. This provided a function for the largest of these (corpus callosum) which had long been conjectural. In the primates, however, it does not connect the visual receiving areas across the midline and there is little evidence to suggest that information can pass from the visual association area to the primary visual receiving area. There seemed a distinct possibility that the visual association area might contain the residual memory store. Experiments designed to test this hypothesis led to the surprising results that, after ablation of this region, a monkey continued to be able to transfer a previously learned ability, and make a given visual discrimination even when the input was confined to the untrained and damaged side. However, such an animal was unable to transfer new discriminations learned through the intact side of the brain. Evidently the memory trace must lie outside the association area removed, but in its absence a new memory trace could not be established through the transfer training technique. However, by restricting the input to that eye which fed into the damaged side of the brain, it was found that the transfer of visual learning from the damaged to the intact side of the brain could still occur.

Using a second group of monkeys, an investigation was made of the role of other neocortical areas in the above experiments (optic chiasma sectioned). All the neo-cortex of the untrained half of the brain was removed except for the primary visual receiving area and motor cortex. When new visual discriminations had been learned on the intact side they did not transfer to the damaged side. The latter could still be trained but usually required about five times as many trials. After training the damaged side it was unexpectedly found that the learned response transferred to the intact side. These experiments showed, therefore, that visual learning does not transfer from the intact half of the brain to that from which most of the cortex outside the primary visual receiving area had been removed. However, if the side sustaining the ablations is trained, the learned response does transfer to the intact side.

A plausible explanation is that when the intact side is being trained the neo-cortex is primarily involved in the learning process. Transfer to the damaged side cannot occur since the neocortical commissures have degenerated. But when the damaged side is trained, sub-cortical structures, probably the hippocampus, sub-serve the learning process and learning transfers to the opposite side via the hippocampal commissures which remained intact in these experiments.

The final talk in the symposium was given by Dr. E. G. Gray (Department of Anatomy, University College, London), who dealt with the relationship between structure and function of the nervous system at a sub-cellular level. He pointed out that during the past ten years electron microscopy has completely changed our understanding of the fine structure of the brain and the all-important transmission regions, the synapses. Before this time, light microscope preparations of silver-stained brain tissues had shown synapses as small bulbs or ring-shaped structures. But the electron microscope has shown that these struc-

tures are fine bundles of protein neurofilaments within the axon and its presynaptic terminal expansion. The light microscope did not show their true shape or the various organelles present at the synapse itself. Most pre-synaptic terminals do not contain neurofilaments and are not observed in silver preparations. Consequently there was a considerable underestimation of the number of synapses in a given region. In particular, the apparent absence of typical synapses in the cerebral cortex caused much embarrassment to theorists on cortical function. However, abundant synaptic contacts in the cortex have now been revealed by the electron microscope.

Electron microscopy has also revealed the presence of numerous synaptic vesicles in the pre-synaptic terminals and it is believed by some that these contain chemical transmitters (acetylcholine at some synapses) which are released into the synaptic cleft by an impulse in the pre-synaptic fibre. Recent work has revealed regularly shaped dense structures at the synaptic membrane and these may function as focal points or pores for the liberation of transmitter substances. Most vertebrate and invertebrate synapses show this chemical-release method of synaptic transmission, but certain specialized synapses depend on direct electrical transmission from pre- to post-synaptic elements without involving a chemical-release mechanism.

In some cases these synapses appear to differ from chemically transmitting synapses in that there is a fusion of the pre- and post-synaptic membranes.

Much morphological variation of pre- and post-synaptic components can be observed with the electron microscope. Especially interesting is the occurrence of numerous spinous outgrowths, once regarded as artefacts in Golgi-method impregnation material, which can be seen to have synaptic contacts at their tip. A peculiar organelle, 'the spine apparatus', occurs within the spine cytoplasm of neurones of the cerebral cortex. Comparable apparatus is not known from other non-mammalian nervous tissue and at present we have no information about its function. Future advances may make it possible to distinguish excitatory from inhibitory synapses and perhaps to detect the sort of structural modifications which probably take place at synaptic membranes during the process of learning.

The whole symposium was concluded by a very profitable discussion. It had certainly given a broad view of the integrative action of the nervous system. Furthermore, as Sir Wilfrid Le Gros Clark pointed out in his final remarks, it had demonstrated the value of the integration of anatomy, zoology and physiology.

G. M. HUGHES

## ACCURACY OF SEA GRAVITY SURVEYS: COMPARISONS OF SHIPBOARD AND SUBMARINE GRAVITY VALUES

By DR. B. D. LONCAREVIC

Bedford Institute of Oceanography, Dartmouth, Nova Scotia

**S**HIPBOARD gravimeter surveys are the latest tool of marine geophysics<sup>1</sup>. The accuracy of any particular survey is very difficult to assess, and very often can only be estimated by intelligent guessing because of the uncertainty of the navigational correction (Eötvös correction)<sup>2,3</sup>. When sufficiently close to land, the ship's position can be determined either by using direct fixes on shore marks or by using precision electronic positioning devices (Decca). An estimate of the accuracy of the shipborne gravimeter can be obtained in this case either by evaluating the gravity differences at track intersections<sup>4</sup> or by comparing shipboard values with those obtained by means of gravimeters placed on the bottom of the sea<sup>5,6</sup>. The latter technique is the only one which provides a means of comparing shipboard values with reference values which are at least an order of magnitude more accurate. However, the bottom gravity measurements can be made only in the depth of water normally found on the continental shelves. Yet the largest part of oceanic survey is carried out over abyssal depths and a method is required for checking the sea gravimeter measurements obtained over the deep ocean.

If a buoy can be placed in deep water and a close survey is carried out within radar range of it<sup>7</sup>, then the accuracy of the sea gravimeter may be evaluated by comparing the gravity values obtained on different tracks at their intersections<sup>8</sup>. This is a special case, and for most oceanic surveys the only available means of checking is to attempt to re-occupy previously established submarine pendulum stations. This article describes the checks during the first two years of operation of a Graf-Askania sea gravimeter by the Department of Geodesy and Geophysics, University of Cambridge.

The method of submarine gravity measurements<sup>9,10</sup> has been established for more than thirty years and the root mean square error of a single station observation has been estimated as  $\pm 3.4$  mgals (ref. 11) or as  $\pm 3.6$  mgals (ref. 12). The main difficulty in using submarine stations

as check points is due to the inherent problem of locating a ship at sea: our methods of celestial navigation have not changed for at least a hundred years. If the weather conditions are ideal and the drift due to currents and wind can be allowed for, then the ship's position can be estimated with an accuracy of 1–2 miles. Viewing conditions are seldom ideal even when the sky is not completely overcast, thereby increasing the error in the estimated position. In the past the location of submarine stations was usually chosen with particular geophysical problems in mind: to investigate the crustal structure over the continental slope, the seamounts, deep trenches or mid-ocean ridges. In each case the horizontal gradients are large, and small error in the position of either the submarine or ship makes comparison between their respective gravity values meaningless. In spite of all the foregoing arguments, re-occupation of submarine stations gives a worth-while check, and should be attempted whenever the research vessel's track can be conveniently arranged to pass near a known submarine pendulum station.

The eastern Atlantic is a particularly good area for checks of the shipborne gravimeter because of the large number of submarine stations which are fairly uniformly distributed. Forty-seven of these stations were re-occupied during the 1960 cruise of R.R.S. *Discovery II* and the 1961–62 cruise of H.M.S. *Owen*<sup>13</sup>. Thirty-eight comparisons were available for evaluation and they are presented in Fig. 1 and Table 1.

The details of comparisons are given in Table 1 so that other investigators can make further checks if there is an opportunity to do so. The serial numbers in column 1 have been arbitrarily assigned. The distances, given in column 5, between the reported position of the submarine station and the nearest approach of the ship's track have a probable error of two miles due to navigational uncertainties in position. The gravity values are the free air anomalies and the three values given for the ship are 10 min (1.5–1.8 nautical miles) readings around the

a, W2833 is 13 miles from B11 but 39 mgal lower. b, 12 mgal difference for a repeat measurement. Depths at two stations 2 miles apart were 4,237 m and 3,672 m. c, Two submarine stations close together. d, See discussion in text. e, Large local gradient due to topography. This value ignored in calculation of root mean square error. f, Near the shelf break; large gradient. g, H263 in 625 fathoms and VM 22 in 1,020 fathoms of water. The depths corresponding to three ship values given were 870, 810, 780 fathoms respectively. If both submarine and shipboard gravity values are plotted against depth, they all fall on a straight line.

nearest approach. From these three readings horizontal gradients along the ship's track can be estimated.

All the shipboard measurements were made with the Askania-Graf GSS 2 sea gravimeter serial No. 11. In 1960 this gravimeter was mounted on a prototype gyro-stabilized platform built for Dr. A. Graf by the Anschütz G.m.b.H. of Kiel, Germany, and owned by the Deutsches Forschungsgemeinschaft. The measurements since 1961 have been performed with the gravimeter mounted on the

Fig. 1. Cumulative percentage error for shipborne sea gravimeter measurements. —, Differences as given in Table 1, — — —, differences if ship track adjustment up to 10 min allowed; . . . , ref. 4

new Anschütz platform<sup>14</sup>. The navigation during all cruises was by celestial fixes only. The positioning of H.M.S. *Owen* was superior to that of R.R.S. *Discovery II*; in the former ship the navigating officer was fully engaged in estimating the ship's position while in the latter ship navigation was done by the officer on watch.

The more accurate results of the 1961 cruise are probably due to both the advanced design of the platform and the better navigation. The root mean square error for 1960 comparisons is  $\pm 12.3$  mgals while the root mean square error for 1961 comparisons is only  $\pm 7.1$  mgals. Considering all the differences given in Table 1, 13, or 34 per cent, were less than 3 mgals and 30, or 79 per cent, were less than 10 mgals. If the differences are adjusted by allowing a 10-min error in the ship's track then 14, or 37 per cent, checks were within 1 mgal; 34, or 90 per cent, were within 10 mgals. The shipboard values are known to have an uncertainty of 3-5 mgals due to difficulties in evaluating the Eötvös correction<sup>5</sup>. The conclusion is, therefore, that there is no evidence for large systematic errors (as suspected by the theory of cross-coupling<sup>15</sup>), and if the means of navigation of research ships at sea could be improved shipborne gravimeters would be more accurate than the submarine pendulums.

Fig. 1 illustrates the percentage error which might be expected from a large number of measurements. Two curves are given for submarine checks. One curve is

calculated on the basis of the estimated nearest approach of the ship's track to the submarine station. The other curve is based on the 10-min adjustment of the ship's track and selection of the shipboard gravity value within 10 min of the nearest approach which gives the smallest difference. For comparison, a percentage error curve for track intersection comparisons off the coast of Southern California is also shown in Fig. 1. (This is curve 2 from Fig. 2 of ref. 4, which is the most extensive evaluation published and refers to a LaCoste and Romberg sea gravimeter.)

Before concluding this discussion, it might be useful to consider the assumptions made in estimating the accuracy of submarine gravity values<sup>11,12</sup>. This accuracy is based on the evaluation of known experimental errors. However, submarine measurements are isolated values and the possibility of a gross error cannot be discounted. The source of such an error might be an undetected malfunction of a part of the equipment or a blunder in calculation. An isolated erroneous value might not look odd and therefore would not be questioned. The particular case in point is Vening Meinesz Station No. 489. This station was approached within 7 miles by R.R.S. *Discovery II* (Ser. No. 16) and within 4 miles by H.M.S. *Owen* (Ser. No. 23). While the two shipboard values agree within 7 mgals, they are both more than 45 mgals higher than the submarine value. The reasonable conclusion is that the submarine value is in error and one is left with a question: How many of the extreme differences in Table 1 are due to unsuspected gross errors in the submarine gravity measurements? It will not be possible to answer this question until the accuracy of shipborne gravimeters can be ascertained by independent tests.

The work described here was carried out under the supervision of Mr. B. C. Browne while I was working in the Department of Geodesy and Geophysics, University of Cambridge. Financial support was provided by grants from the Department of Scientific and Industrial Research and from the U.S. Office of Naval Research under contract N 62558-3542 with the University of Cambridge.

I thank the Master, R.R.S. *Discovery II*, and the Captain, H.M.S. *Owen*, for the use of ships and for their co-operation.

## GEOCHEMICAL APPLICATION OF SPARK SOURCE MASS SPECTROGRAPHY

By PROF. S. R. TAYLOR

Departments of Geophysics and Geochemistry, Institute of Advanced Studies, Australian National University, Canberra

**A**NALYTICAL methods capable of determining elements in geological materials in the concentration range from 0.001 to 10 parts per million have become necessary for the examination of many geochemical problems. The distribution of elements such as thallium, caesium, hafnium and the rare earths can provide sensitive indexes of fractionation processes in the Earth's crust<sup>1</sup> and rapid methods of analysis are urgently needed to determine their abundances in a wide variety of rocks and minerals. The geochemistry of some thirty additional elements is virtually unknown, but doubtless many interesting problems remain to be uncovered. Ehmman<sup>2</sup>, for example, has suggested that the rare element, iridium, would be a better indicator of meteoritic contribution to terrestrial materials, such as impact glasses, than the commonly used nickel. In summary, methods for the determination of about half the chemical elements are required.

The growing industrial demand for materials with impurity concentrations of the order of a part per million, as in semiconductors<sup>3</sup>, has led to the development of mass spectrographs using spark excitation of solid samples. Impurities added from reagent chemicals are thus avoided and the material is analysed with a minimum of processing.

The success of these instruments in determining a wide range of trace elements in a variety of materials<sup>3-7</sup> encouraged the application of this technique to the analysis of geological materials, and a spark source mass spectrograph (type M.S. 7) manufactured by Associated Electrical Industries, Manchester, was installed in this Department

in July 1964 for this purpose. General descriptions of the instrument have been given by several workers<sup>3-7</sup>. A vacuum spark is used to produce a beam of positive ions, largely because it provides roughly equal sensitivity for all elements. The source parts are constructed of tantalum. Ions produced in the spark discharge are accelerated through a series of slits by a potential difference of 20 kV. A double focusing electrostatic and magnetic analyser system, based on the design by Mattauch and Herzog<sup>8</sup>, is used. This design compensates for the wide spread of ion energies produced in the spark source and brings ions to focus in one plane enabling a photographic plate to be used to detect them.

A full description of the instrument and the analytical technique will be published elsewhere; a brief account is as follows: the powdered-rock sample is mixed with an equal weight of National Carbon SP-1 graphite powder, and briquetted in a small laboratory press to form a rod 20 mm × 2 mm × 2 mm. This is trimmed to a cylindrical form with a diamond-tipped tool in a small lathe, to remove possible surface contamination. Two of these rods are clamped in the electrode holders in the source. Since only a few mg of sample are consumed for the longest exposures, careful attention to mixing and sampling procedures is required. To achieve the requisite detection limits pressures of the order of 10<sup>-6</sup> mm mercury (torr) are required in the analyser region. A spark voltage of 25 kV is applied and graded series of exposures are recorded, the pulse length and repetition rates of the spark being increased for larger exposures. Because of the instability of the spark discharge, exposure is measured

Fig. 1. Intensity-concentration graph for the determination of uranium using  $^{235}\text{U}$  and  $^{28}\text{Si}^+$  as internal standard. The points labelled 100 p.p.m. refer to standards containing that amount of uranium

in terms of the total integrated ion current. The instantaneous ion current is of the order of  $10^{-12}$  amp for short exposure conditions, rising to about  $10^{-9}$  amp when large exposures are recorded. The shortest exposure is commonly  $10^{-12}$  coulombs and the longest  $3 \times 10^{-6}$  coulombs. The time varies from a few seconds for the shortest exposures to 2-3 h for the longest. Mass spectra are normally recorded in the range 7-240 mass units, enabling recording of nearly all elements during a single exposure. The photographic plates used are Ilford Q-2, and these are developed in Kodak 'D-19' developer for 2 min and fixed for 1 min in Kodak rapid liquid fixer. These Schumann-type plates are very sensitive to abrasion and require careful handling and storage. The density of the mass lines is read using a Jarrell-Ash microphotometer. Densities are converted to intensities using a plate calibration curve constructed from the densities of  $^{171}\text{Yb}$  and  $^{173}\text{Yb}$ , which have an intensity ratio of 1.52. The photographic calibration curve is an elongate S shape with a small linear portion. Use is made of a seidel function to obtain low-intensity values. Background intensities are subtracted from line intensities where necessary, although the line to background ratio is commonly better than 0.9. Silicon is used as an internal standard and the intensity values of other lines are ratioed to that of the line at mass 9 $\frac{1}{2}$  due to  $^{28}\text{Si}^{3+}$ . Work is proceeding on the use of other internal standards.

The intensity values are plotted against concentration for known standards. Initial tests were carried out using well-established values for elements in the standard granite G-1 and diabase W-1. Although these indicated the general feasibility of the method, reliable values for many of the elements of interest are too few<sup>9</sup>, and artificial standards using the purest oxides where available were prepared, using a base of high purity quartz. A typical intensity versus concentration graph is shown in Fig. 1, for uranium.

The results for a number of elements based on similar graphs are given in Table I for G-1 and W-1. Comparison of these results with the wide scatter of values reported by Fleischer and Stevens<sup>9</sup> is beyond the scope of this article. The general order of magnitude agreement is considered very satisfactory and the instrument seems to be capable of approaching the accuracy of other methods. The linearity of the intensity-concentration relation noted over several orders of magnitude is encouraging.

A detailed discussion and comparison with data of other workers will be presented elsewhere.

The results for the odd-numbered rare earth elements are plotted against results obtained by neutron activation methods by Haskin and Gehl<sup>10</sup> in Fig. 2. There is general agreement between the two sets of data, although some differences in detail.

The precision of the method is being evaluated but it appears to be of the order of 10 per cent. The instrument shows rather uniform sensitivity, with variations up to a factor of three or four. Work is proceeding on the factors responsible and preliminary data indicate a dependence both on volatility and ionization potential. Readily volatile and easily ionized elements such as the

Fig. 2. Comparison of values for the odd-numbered rare earth elements by spark source mass spectrography (open circles—Taylor) and neutron activation analysis (filled circles—Haskin and Gehl, ref. 10)

alkalis show increased sensitivity. Other readily volatile elements, such as thallium, lead and antimony, which possess high ionization potentials, are less sensitive. The least sensitive appear to be the involatile elements such as titanium and zirconium.

Interferences in the mass spectra result from: (1) lines due to multiply-charged ions appearing, for example, at half the mass number for doubly-charged ions: the overall distribution pattern of the elements with decreasing abundances in the higher mass regions tends to minimize, but not remove, this effect: examples of interference are  $^{69}\text{Ga}^+$  by  $^{138}\text{Ba}^{2+}$  and  $^{45}\text{Sc}^+$  by  $^{90}\text{Zr}^{2+}$ ; (2) multiple ion formation. Under the sparking conditions used, there is a relatively low production rate of multiple ions, except for carbon, where lines appear at each multiple of twelve, up to the high mass numbers. It has so far proved possible to avoid the use of these mass numbers, and the resolution of the instrument is commonly sufficient to resolve ion lines of the same nominal mass.

The instrument is thus well suited to the determination of the rarer elements in geological materials, particularly those with isotopes of mass greater than 90. The lighter rarer elements, lithium and beryllium, suffer interference from multiply-charged silicon and aluminium, but boron can be determined using  $^{11}\text{B}$ .

## SOME MEASUREMENTS OF THE TENSILE STRENGTH OF DRY POWDERS OF IRREGULAR PARTICLE SHAPE

By B. B. MORGAN

British Coal Utilisation Research Association, Leatherhead, Surrey

**D**URING the course of a general programme of research aimed at furthering the understanding of the flow of coal through bunkers we have observed that the irregularity of particles has a profound effect on the tensile strength of a powder packing. The measurement of tensile strength has been made using a split tilting-plate apparatus based on that described by Thouzeau and Taylor<sup>1</sup>: some control of the packing density of a powder has been achieved by a tamping procedure devised by J. C. Richards of these laboratories. The powders were of graded particle size and measurement was carried out in the open laboratory at relative humidities mostly in the range 30–55 per cent.

The form of variation in tensile strength as a function of packing density (fractional solids content of the packing), and the effect of particle size, are illustrated in Fig. 1 for a low-rank bituminous coal of National Coal Board Coal Rank Code No. (CRC) 900. In Fig. 2, results for 5–20 $\mu$  fractions of three coals are compared with those for similarly sized alumina and silica powders; a broadly similar pattern of curves, but at higher packing densities, was obtained with 20–33 $\mu$  sieved fractions. In contrast to the behaviour of these five materials of irregular particle shape, the cohesion of copper and glass spheres was found to be so small that they did not form packings sufficiently cohesive for readings to be taken.

The range of packing densities achieved with the tamping procedure varied both with the particle size and with the material, and the densities are all much lower than the value of 0.63 exhibited by 20–33 $\mu$  glass spheres and 5–20 $\mu$  copper spheres. While all the tensile strength curves are of similar shape, those for coals tend to fall to zero more quickly than those for silica and alumina. Tensile strength increases with the fineness of the powder but there is no simple relation, the relative cohesiveness of two powders varying widely with the packing density at which comparison is made. The 20–33 $\mu$  and 5–75 $\mu$  fractions of coal CRC 900 have specific surfaces that are almost equal in value and their tensile strength curves lie close together: thus size dispersion does not appear to affect tensile strength critically.

In view of the low cohesiveness of spherical particles, the results were examined for evidence of a dependence of tensile strength on particle shape. A simple measure of the shape of particles is afforded by comparing the esti-

mates of particle size yielded by different methods of sizing. For the present powders, the surface mean specific surface diameter  $d$  has been determined by the air permeability method and the surface mean projected diameter  $d_p$  of settled particles by the optical microscope method. The ratio  $d_p/d$  is a 'shape factor' that is expected to be unity for spheres and to increase with the degree of particle irregularity. Experimental values are shown in Table 1, that for copper spheres having been included as a check on the reliability of the procedures. Each value is a mean for at least three different size fractions in the overall range 5–75 $\mu$ , there being no evidence of any marked change of shape with particle size.

Table 1. PARTICLE SHAPE FACTOR  $d_p/d$

Material	Copper spheres	Silica	High-rank bituminous coal (CRC 301B)	Anthracite (CRC 101)	Alumina	Low-rank bituminous coal (CRC 900)
Ratio $d_p/d$	1.0	1.9	2.1	2.3	2.6	2.9

The results of Table 1 show the low-rank coal and alumina to have the most irregular particles and it is these powders that exhibit the highest tensile strengths at a given packing density. While these findings are in qualitative accord with a hypothesis of a shape dependence of tensile strength, too much should not be made of the precise numerical values of Table 1. A material has as many shape factors as there are pairs of ways of measuring particle size, so that a factor is in no way a unique characterization of shape. A single factor would not, for example, differentiate between needle-shaped particles and flaky ones, yet their tensile strength behaviour might well be very different. One might question also the choice of air permeability as one of the methods of size determination since it makes use of a powder packing. The present shape factors could conceivably, therefore, have been influenced by tensile strength—although the independence of particle size suggests that in fact they were not.

Visual examination of the low-rank coal confirms the presence of appreciable quantities of needle- and disk-shaped particles. At granular sizes these have been separated from the more rounded particles by sieving on a combination of square-aperture and slot-aperture meshes. If slot-aperture meshes become available at finer sizes it should be possible to test for the effects of

Fig. 1. Tensile strength of coal powder (CRC 900)

particle shape on powder properties more decisively than at present.

Theoretical expressions for the tensile strength of packings of monosize spheres have been given by Rumpf<sup>2</sup> and by Smalley and Smalley<sup>3</sup>, but the relationships they predict bear little resemblance to those we have found for irregular particles. Our results suggest that the challenge to theoretical analysis is considerable. An adequate treatment would have to explain why the relative cohesiveness of two powders of different particle size, but of the same shape, changes so markedly with packing density

Fig. 2. Tensile strength of 5-20 $\mu$  powders

and also the mechanism by which shape affects behaviour. At the present time it is difficult to see how a simple pattern can be imposed on the results unless the practice of making comparisons at equal packing densities is abandoned.

The measurements of tensile strength were made by Mr. A. C. Chilton.

## INHALATION AND RETENTION OF FALL-OUT ZIRCONIUM-95 BY HUMAN BEINGS

By J. RUNDO and D. NEWTON

Atomic Energy Research Establishment, Harwell, Berks

IN 1962 we reported<sup>1</sup> the detection of  $\gamma$ -rays at about 0.76 MeV from the chest region of all human subjects. We attributed this radiation to the presence of the fission product zirconium-95 (half-life 65 days) accompanied by its daughter-product niobium-95 (half-life 35 days), both of which emit  $\gamma$ -rays having energies between 0.72 MeV and 0.77 MeV. These radio-nuclides and other fission products had been found in human lungs examined *post mortem*, notably by Schönfeld *et al.*<sup>2</sup>

In this article we wish to report the results of our measurements of zirconium-95 in human lungs *in vivo* up to October 1963 and of our attempts to correlate the levels observed with the amounts in the air breathed. We may recall that the method of measurement involved the determination of the  $\gamma$ -ray spectrum with a 23-cm

diam. crystal of sodium iodide (TI) placed 2 cm below the thorax of the supine subject. The  $\gamma$ -ray spectra were analysed by a computer method of least squares using standard spectra from potassium-40 and caesium-137 and from zirconium-95/niobium-95 in a low-density lung phantom<sup>1</sup>.

Since these measurements began the amounts of both zirconium-95/niobium-95 and caesium-137 *in vivo* have shown substantial changes, as illustrated by the results in Figs. 1 and 2. In Fig. 1 are shown parts of the  $\gamma$ -ray spectra (0.5-0.9 MeV) from the thorax of Mrs. M. N. on four occasions at intervals of six months. In each case the spectrum derived by the computer has been drawn as a smooth curve; the agreement between the fitted curves and the experimental points is good even in the measure-

Fig. 1. Parts of the  $\gamma$ -ray spectra (0.5-0.9 MeV) from the thorax of Mrs. M. N. on four occasions at intervals of six months. A, April 21, 1962; B, October 20, 1962; C, April 24, 1963; D, October 6, 1963

ment of April 21, 1962, when the gain of the system was slightly different from normal. The values for the zirconium-95/niobium-95 content of Mrs. M. N., together with those for three other subjects, are plotted as a function of time in Fig. 2. The activities in all four subjects show the same trend, namely, a minimum in the autumn of 1962 and a maximum in the spring-summer of 1963. There seems to be a correlation between lung content and body-weight, as well as a possible sex difference. After October 1963 the effects of increasing whole-body contents of caesium-137 and decreasing lung contents of zirconium-95 combined to make the estimates of the latter nuclide quite unreliable.

A qualitative explanation for the fluctuations in the caesium-137 and zirconium-95/niobium-95 contents of the body, and for the differences between the two, is provided by the data plotted in Fig. 3. They are: (a) the quarterly mean concentrations of caesium-137 (from world-wide fall-out from nuclear test explosions) in milk produced on farms close to this Establishment<sup>3</sup>; (b) the monthly mean concentrations of zirconium-95 in air at ground-level at Chilton, Berks<sup>4</sup>. Because of the relatively short half-life of zirconium-95 (65 days) the levels *in vivo* followed quite closely the levels in the air. (It must be pointed out here that the measurements *in vivo* were of zirconium-95 with its daughter niobium-95 not necessarily in radioactive equilibrium, whereas the levels in air were determined when the niobium-95 had almost reached equilibrium with the parent

zirconium-95.) In the case of caesium-137 with its long half-life for radioactive decay, and an average biological half-life in adult man of about 100 days<sup>5</sup>, the levels *in vivo* at any time reflect the average levels in the diet over the preceding few months. We shall not consider further the caesium-137 levels *in vivo* as our results have been published<sup>6</sup>.

*Estimation of zirconium-95 present.* As already pointed out here, the measurements *in vivo* were of the total  $\gamma$ -ray activity of a mixture of zirconium-95 and its daughter niobium-95. In order to convert the measured

Fig. 2. The total  $\gamma$ -ray activity due to zirconium-95 and niobium-95 in the lungs of two men and two women as a function of time (April 1962-October 1963)

Fig. 3. Quarterly mean concentration of caesium-137 in milk produced on farms near Harwell (dashed line) and the monthly mean concentration of zirconium-95 in air at ground-level at Chilton, Berks (solid line)

activities into zirconium-95 activities, it was necessary to know the values of the ratio:

$$R_{\gamma} = \frac{\text{number of } \gamma\text{-rays at 0.76 MeV}}{\text{number of } \beta\text{-particles from Zr-95}}$$

at the various times the measurements were made. Provided that these were not too soon after a series of atmospheric nuclear weapon tests, a mean effective date of production could be assumed, and values of  $R_{\gamma}$  could be calculated easily. This was the situation for measurements made between January and July 1962 of zirconium-95 produced in September and October 1961, and for measurements made between January and July 1963 of zirconium-95 produced in the autumn of 1962. However, when the measurements were made shortly after the commencement of a test series the determination of  $R_{\gamma}$  for the  $\gamma$ -ray activity actually in the lung was more difficult. This was the case for our measurements in October 1962; it can be shown that in that month only about 9 per cent of the airborne zirconium-95 originated from the 1961 test series whereas it seemed unlikely that less than about 65 per cent of the lung content in October 1962 originated from the 1961 series (see following). An accurate value for  $R_{\gamma}$  could not therefore be determined; for the zirconium-95 inhaled during the month, a value of 1.73 would be deduced, whereas for the zirconium-95 in the lung a value somewhat below 3.0 would be reasonable. It is worth noting that immediately after fission,  $R_{\gamma} = 1$ , whereas when niobium-95 is in equilibrium with the parent,  $R_{\gamma} = 3.14$ .

In Table 1 are set out the average values for the total  $\gamma$ -ray activity and the zirconium-95 activity in subjects measured at intervals between January 1962 and October 1963, together with the values assumed for  $R_{\gamma}$ . No errors are shown; the statistical standard error on a single observation was in the range  $\pm 15$  to  $\pm 20$  per cent, while biological variation can cause a substantial spread in the results as indicated in Fig. 2. As we suggested in our previous report<sup>1</sup>, there may be a systematic error due to the method of calibration. The only possible way of assessing this is by comparison with the results of others

Table 1. AVERAGE VALUES FOR THE TOTAL ACTIVITY AT 0.76 MEV AND THE ZIRCONIUM-95 ACTIVITY IN THE LUNGS OF CONTROL SUBJECTS, JANUARY 1962-OCTOBER 1963

Date	No. of subjects	Total activity at 0.76 MeV (pc.)	$R_{\gamma}$ (in vivo)	Zirconium-95 content of lung (pc.)
January 1962	10	~300	2.3	~130
April 1962	14	355	2.75	129
July 1962	13	238	3.0	79
October 1962	16	205	<1.7	>120
Nov./Dec. 1962	7	280	~2.3	<68
Jan./Feb. 1963	9	376	2.6	~120
April 1963	12	450	2.8	145
July/Aug. 1963	12	447	3.0	161
October 1963	11	226	3.1	149

who have analysed lungs obtained *post mortem*. The data are very sparse, but in general our results agree well with those of Schönfeld *et al.*<sup>2</sup>, Osborne<sup>7</sup>, Wegst *et al.*<sup>8</sup> and Passant *et al.*<sup>9</sup>, and it seems clear that any systematic errors in our method of calibration must be quite small (< 20 per cent).

**Calculated lung contents.** From the monthly mean concentrations of zirconium-95 in air at ground-level<sup>3</sup> it should be possible to calculate values for the lung contents, with the aid of suitable models. Comparison with the observed contents may indicate which model best fits the facts. As a starting-point we used the single exponential model of the International Commission on Radiological Protection (I.C.R.P.)<sup>10</sup>; the lung content  $q$  pc. is given by the equation:

$$q = \frac{fCVT}{0.693} \left[ 1 - e^{-\frac{0.693t}{T}} \right] \quad (1)$$

after inhalation for  $t$  days of  $C$  pc./m<sup>3</sup> of air, where  $V$  is the breathing-rate in m<sup>3</sup>/day,  $f$  is the fraction of the inhaled material which is not exhaled or removed rapidly by ciliary action from the upper respiratory tract and  $T$  is the effective half-life in days. Inserting the values recommended by the I.C.R.P. of  $f = 0.125$ ,  $V = 20$  m<sup>3</sup>/day and  $T = \frac{T_b T_r}{T_b + T_r} = \frac{120 \times 65}{185} = 42$  days, and using the

values of  $C$  plotted in Fig. 3, the content of the lung at the end of each month due to zirconium-95 inhaled during that month was calculated. The fractional decrease per month caused by an effective half-life of 42 days was then applied repeatedly, in order to calculate the amounts remaining in the lung at the end of successive months. Finally, the amounts for individual months were summed to give the totals for those months; the results are plotted in Fig. 4 (lower curve, labelled 'I.C.R.P. model'), where the experimental results of column 5 of Table 1 are also plotted. This model underestimates the lung content by

Fig. 4. Comparison of observed lung contents of zirconium-95 with contents calculated from the data in Fig. 3 on the basis of two different models for the retention in the lung

a factor of between two and three; also, it will be seen that the values of the calculated maxima in January/February 1962 and in April/May 1963 were both close to three times the minimum value in September/October 1962 whereas the observed maximum values were not more than twice the minimum. This suggests that the value for the effective half-life was too low.

The calculation of lung contents was next repeated with extreme values for the variables in equation (1). Thus  $f$  was assumed to be 1.0, and  $T$  was taken as 65 days (that is, no biological elimination from the lung);  $V$  was still taken as 20 m<sup>3</sup>/day. The observed average lung content at any time was expressed as a fraction of the maximum possible calculated value to give a series of estimates of  $f$ . The average of these (excluding that for October 1962, because of the uncertainty already discussed) was 0.25 and this value was then applied to the maximum possible lung contents (that is, those calculated with the assumption of  $f = 1.0$ ). The values obtained in this way are also plotted in Fig. 4; since the breathing rate is not known precisely the model is more correctly described as one in which  $fV = 5.0$  m<sup>3</sup>/day, rather than one in which  $f = 0.25$ . With the exception of the results for November/December 1962 and January/February 1963 the observed average lung contents agree with the calculated to within about  $\pm 20$  per cent. The discrepancies for the measurements during the winter of 1962-63 cannot be explained; possible causes might include such factors as variations in particle size and density, relative humidity and temperature of the air and breathing rates.

The conclusion which we may draw from these results is that use of the I.C.R.P. model for the retention in the lung of small ( $< 1\mu$ ) particles underestimates the actual lung content by a factor of 2-3, and the biological half-life of 120 days seems to be much too short. Unfortunately our results do not permit us to deduce a reliable value for the biological half-life. One way in which this might be estimated is by the determination of the lung content of one of the longer-lived fission products such as ruthenium-106 and cerium-144, and comparison with the calculated contents from the air-levels. These radio-nuclides could not be detected *in vivo* by external counting<sup>1</sup> but were determined in excised lungs examined *post mortem*<sup>2,3</sup>.

Finally, it is worth noting that our conclusion that the biological half-life is much longer than 120 days is not incompatible with our observation<sup>1</sup> that the average lung content of zirconium-95/niobium-95 of three men in April 1962 was 28 times their daily faecal excretion of these nuclides. Taken at its face value, this could imply that the biological half-life in the lung was only 19 days if: (a) a single exponential function describes completely the retention of all material deposited in the respiratory tract; (b) all the faecal activity were due to material which had been inhaled and then removed from the lung by ciliary action and swallowing, and none to ingested material. Even if condition (b) is valid it is easy to show that a value of 28 for the ratio mentioned here is obtained with a two-component exponential function to describe the lung retention. For example, with biological half-lives of 1 day and 250 days the fractions moving at these rates would be 0.05 and 0.95 respectively. A half-life of about 1 day is not unreasonable for the phase of rapid clearance by ciliary action, while we obtained a value of 250 days for the long-term clearance of zirconium-95 in one case, following inhalation of irradiated uranium<sup>11</sup>. It should not be assumed that 250 days is necessarily the biological half-life for inhaled fall-out zirconium-95; we merely use this to show that if a few per cent of the inhaled material had a very short half-life and the remainder a long half-life, then the excretion rate would be such as to suggest a short half-life (that is, 19 days) with assumptions (a) and (b) above.

## ABSCOPAL STIMULATION OF THE THYMUS OF RATS BY EXPOSURE OF THE HEAD TO X-RAYS

By MRS. DALIA MAOR

Radiolotope Training Center, The Weizmann Institute and the Israel Atomic Energy Commission, Rehovoth, Israel

AND

DR. PETER ALEXANDER

Chester Beatty Research Institute, Institute of Cancer Research: Royal Cancer Hospital, London, S.W.3

THE appearance of radiation changes in organs remote from those that have been exposed to ionizing radiations has frequently been claimed, and the phenomenon has been called 'abscopal'<sup>1</sup>. Loss of weight of spleen and thymus has been observed<sup>2</sup> after part-body irradiation, but was attributed to general malaise<sup>3</sup>. Recently such changes were seen four days after exposure of small parts of the abdomen of mice<sup>4</sup> when the animals did not appear to be sick. Benjamin and Yost<sup>5</sup> found a decrease in oxidative phosphorylation of the spleen after irradiation of the head of animals. We<sup>6</sup> observed marked increases in the content of alkaline ribonuclease (RNase) in the spleen and thymus of rats the heads of which had been exposed to 1,000 r. of X-rays. The measurements made are believed to represent the total RNase activity of the organs, since the cells were completely disrupted by repeated freezing

and thawing before enzyme assay. The increased RNase activity was seen in the spleen within a few hours after head irradiation, but was not pronounced in the thymus until more than 24 h had elapsed. Elevation of the RNase activity of the thymus following whole-body irradiation of mice was first reported by Weymouth<sup>7</sup>, and our experiments indicated that part of this effect was abscopal and could be attributed to exposure of the head.

We have now found that the rise in RNase due to head irradiation is preceded by an increase in the rate of incorporation of radioactive thymidine into the DNA of the thymus, though not of the spleen.

**Experimental procedures.** 24-28-day-old rats, ranging in weight from 42 to 50 g, were placed in a coffin-shaped lead box from which only the head protruded. To determine the effectiveness of the shielding a 'Victoreen' dose meter

Table 1. EFFECT OF HEAD IRRADIATION AND STRESS ON SPLEEN AND THYMUS OF RATS (AVERAGE OF AT LEAST FIVE RATS PER GROUP)

Treatment	Age (days)	Weight (g)			DNA content (mg)		RNase $\mu$ g of organ		Thymidine uptake $\dagger$

was placed in the thymus and spleen in the carcass of a rat. 280-kV X-rays (no filter) were used at a dose rate of 250 r./min. The dose received by the spleen was less than 0.5 per cent, and that by the thymus was 1.2 per cent, of that received by the head. The experimental procedures for determining RNase were as described earlier<sup>6</sup>, but the present series differs in that four-week-old rats were used instead of eight-week-old rats weighing 110 g, so as to conserve radioactive thymidine. The rate of thymidine incorporation was measured by intraperitoneal injection of 1  $\mu$ c./g body-weight of tritiated thymidine with an activity of 8.8 curie/m.mole 15 min before killing the animals. The DNA from the thymus and spleen was then separated by extracting the tissues with cold 15 per cent trichloroacetic acid and then hydrolysing the precipitate. The radioactivity of the hydrolysate was measured in a scintillation counter.

**Increase of DNA synthesis in the thymus.** Table 1 shows that 24 h after irradiating the head of rats with 1,000 r. there is a pronounced increase in the rate of incorporation of thymidine into the DNA of the thymus and in the RNase content of the spleen. The RNase activity of the thymus is also substantially higher at 24 h, but the dramatic increase is only seen later in this organ (see Fig. 1). Table 1 shows that these effects of head irradiation are not produced by generalized stress such as loading the animals into the irradiation container, starvation, or injection of ACTH. Irradiation of the hind legs does not produce the abscopal effects seen in spleen and thymus after head irradiation. No change whatsoever was observed in thymidine incorporation or RNase activity in the liver at 24 and 48 h following 1,000 r. to the head.

Fig. 1 shows the development of these changes with time after 250 r. to the head. Increase in thymidine uptake in the thymus is already apparent at 2 h, and at 19 h the rate is close to its maximum value. The effect begins to disappear on the fourth day after irradiation. It is noteworthy that no significant change in the thymidine uptake of the spleen could be observed at any time although in this organ the RNase content was greatly increased by head irradiation. Changes in splenic RNase seem to occur a few

hours later than the increase in thymidine incorporation in the thymus, but are close to their maximum at 24 h. The increase in thymic RNase occurs later, and with a dose of 250 r. is not significant 24 h post-irradiation. In Table 2 the effects of different doses of head irradiation are compared; the data suggest that the enhancement of thymidine incorporation becomes independent of dose after 250 r., while the effect on the RNase content shows no indication of levelling off below 1,000 r., the highest dose examined.

The increased rate of thymidine incorporation is unlikely to be a pool-dilution phenomenon, since it is independent of the amount of radioactive thymidine injected, and it probably represents a true increase in the rate of DNA synthesis of certain thymus cells after head irradiation. Histological examination showed an increase in the number of dividing cells in the thymus after irradiation, and it seems probable, therefore, that the thymidine incorporation measurements reflect a true stimulation of cell division in the thymus by exposure of the head of young rats to X-rays. The rise of RNase which occurs much later in the thymus would appear to be a result of the stimulation and may be related to the return of the rate of cell division to normal.

The effect of head irradiation in the RNase content of the spleen appears to be mediated by the thymus since it

Fig. 1. Changes in the rate of thymidine incorporation ( $\Delta$ ) and in the content of RNase ( $\circ$ ) of spleen and thymus at different times after exposure of the head (only) to 250 r. of X-rays (each point is the average of measurements on five rats)

is largely abolished in animals that have been thymectomized (see Table 1). The thymus may exert an action in the spleen by excretion of humoral factors, and this form of control may be altered by head irradiation. Another interpretation is that head irradiation induces a discharge of cells from the thymus to the spleen and that on reaching the spleen these cells undergo changes which are accompanied by an increase in RNase. This hypothesis would explain why the number of cells in the thymus (that is, the DNA content of the organ) is not increased after head irradiation (see Table 1) in spite of the fact that the thymidine uptake data indicate a very large increase in the rate of cell division in this organ. Indeed, our data (see Table 2) consistently show some fall in the total content of thymus DNA after head irradiation though the magnitude of this decrease is too small to be reliably interpreted since changes due to anorexia are to be expected.

The mechanism by which exposure of the head stimulates cell division of the thymus is obscure. The experiments shown in Table 1 establish that it is not a normal

stress phenomenon following on an increase in the secretion of ACTH. In this connexion the finding of Hameed and Haley<sup>8</sup> may be relevant—that early elevation of plasma corticosterone is obtained only if the body is exposed to X-rays, head irradiation being without effect. We suggest that head irradiation, by stimulation of hypothalamic centres<sup>9</sup> or repression of some hypophyseal function, interferes temporarily with neuro-endocrine factors responsible for controlling the rate of cell turnover in the thymus. Experiments to test this hypothesis are being carried out.

## DISTRIBUTION OF METALS AND CATECHOLAMINES IN BOVINE ADRENAL MEDULLA SUB-CELLULAR FRACTIONS

By DR. J. L. BOROWITZ, K. FUWA and DR. N. WEINER

Department of Pharmacology and Biophysics Research Laboratory, Peter Bent Brigham Hospital, Harvard Medical School, Boston, Mass.

THE ability of adenosine triphosphate (ATP) to chelate many divalent cations is well known. ATP is also able to interact with catecholamines in an ionic linkage reinforced by hydrogen bonding<sup>1</sup>. Since ATP occurs in high concentration in adrenal granules, it appeared possible that a divalent metal might be associated with it in the granules, and that this metal might be involved in the binding or release of catecholamines. For this reason, sub-cellular fractions of adrenal medulla were analysed for a series of multivalent metals.

Fresh adrenal medullae, obtained from cattle at a local abattoir, were homogenized in 0.3 M sucrose, and separated into various sub-cellular fractions using differential and gradient density centrifugation. Aliquots from these fractions were either ashed at 500° C for 2 days, or digested with acid and peroxide. The samples were then analysed for their metal content. In three experiments, multivalent metals were determined using emission spectroscopy<sup>2</sup>. In one experiment, calcium was estimated using absorption spectroscopy, and magnesium was measured by the thiazole yellow method<sup>3</sup>. Results obtained using these methods were in good agreement. The glass distilled water and sucrose used in these experiments were found to contain negligible amounts of metals. Additional aliquots of adrenal medulla fractions were taken for the determinations of protein by the biuret method<sup>4</sup>, catecholamines by the method of von Euler and Hamberg<sup>5</sup>, and succinic oxidase by the manometric method<sup>6</sup>.

Fig. 1 shows the distribution of the three major multivalent metals and catecholamines in sub-cellular fractions of bovine adrenal medulla. The metal content of chromaffin granules is small compared with the concentration of catecholamines present. For example, the ratio of catecholamine molecules to calcium atoms present in chromaffin tissue is about 27. Calcium concentration generally parallels catecholamine concentration in all fractions except mitochondria, where the calcium concentration is relatively high. This is in agreement with the observation that the calcium content of rat liver mitochondria is high<sup>7</sup>. In granules, the calcium concentration is approximately 60  $\mu$ moles/g protein, nearly 2.5 times

that in the total homogenate (25  $\mu$ moles/g protein). In contrast, magnesium, which is the most predominant divalent metal present in adrenal medulla homogenate (41.5  $\mu$ moles/g protein), is found in relatively low concentrations in granules (23.6  $\mu$ moles/g protein).

The concentration of iron in granules averages 3.9  $\mu$ moles/g protein. In the other sub-cellular fractions of adrenal medulla, the distribution of iron parallels that in analogous rat liver sub-cellular fractions<sup>7</sup>. The highest concentrations of iron are found in microsomes and mitochondria in both cow adrenal medulla and rat liver.

A number of other metals were also determined by atomic emission spectroscopy. Zinc was fairly constant at 2  $\mu$ moles/g protein in all sub-cellular fractions of medulla. Chromium, strontium, barium and manganese were found in trace quantities, and were not concentrated in any fraction.

The distributions of catecholamines and succinic oxidase activity in the several fractions of the gradient density tubes show that an almost complete separation of mitochondria from granules was achieved. In each of the four separate experiments, the calcium concentration was greater in granules than in mitochondria. Magnesium, on the other hand, was found in higher concentrations in mitochondria than in granules. In fraction III, containing both mitochondria and granules, the calcium and magnesium concentrations were intermediate between those in mitochondria and in granules (Fig. 2).

The content of calcium in chromaffin granules is especially notable when compared with that of other soft tissue fractions. For example, granules from cow adrenal medulla contain six times as much calcium/g protein as rat liver mitochondria, which, in turn, contain more calcium than any other sub-cellular fraction of rat liver<sup>7</sup>.

It was thought that this large concentration of calcium in granules might be due to chelation by ATP. Calcium, however, forms a chelate with ATP which has a slightly lower stability constant than the Mg-ATP chelate<sup>8</sup>. Since magnesium occurs in high concentration in the supernatant of adrenal medulla, one might expect mag-

Fig. 1. Distribution of metals and catecholamines in total homogenate (TH), nuclei and cell membranes, cell supernatant, microsomes, mitochondria, and chromaffin granules of bovine adrenal medulla

Fig. 2. Distribution of catecholamines, succinic dehydrogenase, calcium, and magnesium in four sucrose gradient density fractions of bovine adrenal medulla. The fractions are: I, supernatant or top; II, mitochondria; III, mixed, containing both mitochondria and granules; IV, granules

nesium to be more concentrated than calcium in granules, if simple sequestration by ATP were the only factor involved.

The ability of granules to take up calcium *in vitro* was tested at various temperatures using radioactive calcium. Approximately 0.2  $\mu$ c. of  $^{45}\text{CaCl}_2$  (0.375 mc./g) was added to 40 ml. of a 10 per cent homogenate (in 0.3 M sucrose) of cow adrenal medulla and a portion of the homogenate was then directly carried through the fractionation procedure at 0° C. Other aliquots were incubated for 15 min at either 4° C or 37° C followed by fractionation at 0° C. Protein was precipitated from aliquots of each fraction with 10 per cent trichloroacetic acid (TCA). The precipitates were washed twice with 5 per cent TCA and the supernatants were combined. Carrier  $^{45}\text{CaCl}_2$  (0.2 mg) was added to the acid extracts and the calcium was precipitated as the oxalate from basic solution. The calcium precipitate was uniformly deposited on a planchet and counted in a gas flow counter (efficiency = 18 per

† No incubation prior to fractionation.

‡ Incubated for 15 min at the temperature noted prior to fractionation.

cent). Results are expressed as the ratio: c.p.m./mg protein sub-cellular fraction : c.p.m./mg protein in the whole homogenate (Table 1).

Calcium-45 is taken up by both mitochondria and chromaffin granules of bovine adrenal medulla at 0° C and at 4° C. At 37° C the mitochondria contain about the same amount of  $^{45}\text{Ca}$ /mg protein as the total homogenate.

The uptake of calcium-45 by chromaffin granules, on the other hand, is relatively independent of temperature. There is no significant difference in the uptake of calcium-45 by granules at any of the three temperatures examined (Table 1). A similar temperature-independent uptake of  $\text{Ca}^{++}$  by polymorphonuclear leucocytes was observed by Woodin and Wieneke<sup>9</sup>.

In another series of experiments EDTA (final concentration,  $10^{-3}$  M) was added to bovine adrenal medulla homogenate and the homogenate was shaken for 15 min in air at 4° C. The subcellular fractions were separated as before and analysed for protein and catecholamines in the usual manner. Calcium was measured in each fraction by atomic absorption spectroscopy. The presence of EDTA resulted in a decrease in the calcium concentration of all particulate fractions and an increase in the calcium concentration in the soluble portion of the cell. The calcium concentration of mitochondria was significantly decreased from  $43.2 \pm 2.7$  S.E.  $\mu$ moles/g protein to  $27.3 \pm 1.5$   $\mu$ moles/g protein. The calcium concentration of chromaffin granules was also decreased from  $67.8 \pm 3.7$  to  $53.4 \pm 3.3$   $\mu$ moles/g protein although this decrease was not statistically significant. It thus appears that most of the calcium of chromaffin granules is firmly bound, and is not affected by the presence of  $10^{-3}$  M EDTA.

Douglas and Poisner<sup>10</sup> showed that the uptake of calcium-45 by isolated perfused cat adrenal medulla is markedly enhanced during stimulation of the gland. The site of intracellular uptake of calcium-45 was not determined in their investigations. It is possible that calcium is taken up by the granules during adrenal stimulation and that this process may initiate the release of catecholamines from their intragranular storage complex. The existence of a high concentration of calcium in the granules is compatible with the theory that calcium is directly involved in intragranular catecholamine release. Woodin and Wieneke have shown that the leucocidin-induced release of leucocyte granule enzymes is markedly increased in the presence of calcium and ATP<sup>11</sup>. The vesicles remaining in the depleted leucocytes contain several times more calcium than granules of unstimulated leucocytes<sup>9</sup>. These investigations suggest that calcium plays a part in the initiation of the release of enzymes from granules of polymorphonuclear leucocytes. Calcium may play a similar part in the release of catecholamines from granules of adrenal medulla.

# EFFECTS OF METABOLIC INHIBITORS ON ENERGY METABOLISM OF EHRLICH ASCITES CARCINOMA CELLS

By DR. I. J. BICKIS and PROF. J. H. QUASTEL, F.R.S.

McGill-Montreal General Hospital Research Institute, Montreal, Canada

**I**N the course of work on the action of anti-cancer agents on metabolism of tumours, *in vitro* routine observations and evaluations have been made of the effects of several well-known metabolic inhibitors on energy-yielding processes and on operations such as protein and nucleic acid biosyntheses in tumours.

It is our objective to present one or two broad generalizations which have come to light as a result of this work.

We have worked largely with ascites tumour cells, which under appropriate physiological conditions are very suitable for such investigations. They provide uniform, highly malignant, cancer cells in which the observed effects of the agents are not obscured by factors such as necrosis and stroma which are commonly encountered in solid tumours.

Animals with 6-8 days old ascites were killed by cervical dislocation and the ascites fluid from the peritoneum was collected with a Pasteur pipette in a graduated centrifuge tube. The cells were washed several times by suspending in ice-cold Krebs-Ringer medium (without buffer or glucose) and centrifuging in the six-place head of the international clinical centrifuge at maximum (800g) speed: once for 1 min and twice for 20 sec. This procedure removed the ascites fluid and blood elements. The re-suspended cells were then centrifuged for 2 min, the supernatant was removed, and the packed cells were re-suspended in nine parts of the same Krebs-Ringer medium. Portions (0.5 ml.) of the final suspension were added to each incubation vessel. Under these conditions 0.5 ml. cell suspension corresponded to approximately 50 mg wet- or 5 mg dry-weight of tumour cells.

It is important that the cell density per vessel in different experiments should be kept constant if comparable results are required. Our observations indicate that the specific activities (that is, activities per unit weight) of measured metabolic processes (respiration, glycolysis, incorporation of radioactivity into proteins) tend to diminish with increasing cell density and that the relative effects of drugs (that is, per cent inhibitions) also decrease. The fact, for example, that the effects of actinomycin D diminish with increased density of cell population of bacteria, or of L cells, has already been reported<sup>1,2</sup>.

The conventional Warburg manometric technique was used for the measurement of respiration and glycolysis. This technique was also used during the estimation of the incorporation of radioactivity of labelled glycine into cell proteins. The Ringer media used were those described by Umbreit *et al.*<sup>3</sup>, except that calcium chloride was present at a concentration of 1.5 mM. Glucose when added was 10 mM. For measuring respiratory rates, the gas phase was air, but aerobic and anaerobic glycolytic rates were measured after appropriate gassing with mixtures of 95 per cent oxygen and 5 per cent carbon dioxide or 95 per cent nitrogen and 5 per cent carbon dioxide respectively. To secure complete anaerobiosis, in some experiments, a stick of yellow phosphorus was placed in the centre wells of the manometric vessels. The drug and any radioactive tracer were placed in the side-arm of the manometric vessel and tipped into the main compartment after 10 min thermal equilibration. The incubation time was normally 1 h at 37° C. The total volume of fluid in the vessels was 3 ml.

Radioactive glycine (glycine-1-<sup>14</sup>C) was used in the experiments described below. Its final concentration in

the manometric vessel was 2 mM. Estimation of its incorporation into the proteins of Ehrlich ascites cell was carried out as described in an earlier paper<sup>4</sup> using a thin window gas flow Geiger-Müller tube and automatic scalar. Weights of proteins from different vessels of the same experiment were approximately the same (3-4 mg) and no correction for self-absorption was necessary. The incorporation of radioactivity into proteins has been calculated in c.p.m./mg protein.

Results of individual experiments are given in Tables 1-3, where for each experiment (consisting of a control and control + inhibitor) a different preparation of Ehrlich ascites cells was used. Each experiment was carried out at least three times, and with any one preparation of ascites cells the deviation from the mean was not greater than  $\pm 4$  per cent.

*Constancy of rates of ATP formation in tumour cells in presence of certain metabolic inhibitors.* We have shown<sup>4</sup> that, in ascites tumour cells, the fall in rate of formation of adenosine triphosphate (ATP) by operation of the Crabtree effect is balanced by an increased rate of formation of ATP by enhanced aerobic glycolysis, that is, the fall in respiratory ATP is compensated by increased glycolytic ATP. Typical results given in Table 1 show that the combined rates of aerobic formation of ATP in the cell (that is, the sum of respiratory and aerobic glycolytic ATP) is a constant, in the presence or absence of a variety of metabolic inhibitors. That is:

$$6Q_{O_2} + Q_{CO_2(O_2)} = K$$

= respiratory ATP,      = aerobic      (constant)  
assuming P/O = 3      glycolytic  
ATP

The results demonstrate that in the presence of a variety of metabolic inhibitors, which affect the energetics of the cell, the generalization holds that, in the tumour in the presence of glucose, loss of ATP by diminished respiration is balanced by an approximately equal gain of ATP by increased aerobic glycolysis and that loss of ATP by inhibited glycolysis is compensated by a gain of ATP by an increased rate of respiration. For example, malonate, diazouracil, chlorpromazine or potassium cyanide, each of which decreases the respiratory rate, increases the rate of aerobic glycolysis, while DL-glyceraldehyde or carzinophilin, each of which decreases the glycolytic rate, increases the respiratory rate (Table 1).

*Effects of 'uncoupling' metabolic inhibitors.* Experiment shows that the total energy made available by respiration and glycolysis in Ehrlich ascites cells respiring in a glucose-Ringer medium is about equal to, though often

Inc. = incorporation of glycine-<sup>14</sup>C into proteins expressed as c/min/mg protein

somewhat higher than, that obtained by glycolysis under anaerobic conditions in a glucose-Ringer medium. This is seen in the various typical values shown in Table 2 and Table 3, where it is clear that the aerobic value  $Q_{ATP}$  calculated as  $2nQ_{O_2} + Q_{CO_2(O_2)}$  (where  $n = P/O$  ratio = 3) is approximately equal to, but usually a little higher than, the anaerobic value of  $Q_{ATP}$  calculated as  $Q_{CO_2(N_2)}$ . This result is consistent with the fact that the incorporation of glycine-1-<sup>14</sup>C into the tissue proteins is approximately the same under aerobic and anaerobic conditions<sup>4</sup> (see also Table 3).

It is possible to arrive at a measure of the amount of uncoupling brought about by a drug that is neither a respiratory nor a glycolytic inhibitor. In the presence of a substance that uncouples phosphorylations from respiration, but is not a respiratory or glycolytic inhibitor, there is an increased rate of aerobic glycolysis. In such circumstances the value of the sum of  $6Q_{O_2} + Q_{CO_2(O_2)}$  may greatly exceed that of  $Q_{CO_2(N_2)}$  (these values being obtained in a glucose-Ringer medium in presence of the drug). For example, the well-known uncoupler 2:4-dinitrophenol at 0.1 mM gives a value of  $6Q_{O_2} + Q_{CO_2(O_2)} = 188$  which is far in excess of the value for  $Q_{CO_2(N_2)} = 74$  (Table 2). This is due to the fact that not only is the aerobic glycolysis increased but the rate of respiration is also increased. The respiratory increase, however, is not coupled with ATP formation and hence the value of  $6Q_{O_2}$  gives a wholly inaccurate measure of the ATP produced in the respiratory process in presence of the dinitrophenol. The coupled  $Q_{O_2}$  would be given approximately by the value  $\frac{Q_{CO_2(N_2)} - Q_{CO_2(O_2)}}{6}$ , taking the P/O ratio for Ehrlich ascites cells as equal to 3 (ref. 4).

This value in the case of 2:4-dinitrophenol (Table 3) at 0.1 mM is  $\frac{73.8 - 63.2}{6} = 1.8$ . This may be contrasted with the value of  $Q_{O_2} = 20.8$  obtained aerobically in a glucose-phosphate medium (Table 3). The difference between the two values, that is,  $20.8 - 1.8 = 19.0$ , may be regarded as a measure of the uncoupled rate of respiration, that is, a measure of the amount of oxygen consumption that is ineffective as a source of energy to the cell.

The value of  $n$  (that is, the P/O ratio) of the Ehrlich ascites cells in presence of glucose and an uncoupling agent may be estimated using the expression:

$$2n = \frac{Q_{CO_2(N_2)} - Q_{CO_2(O_2)}}{Q_{O_2}}$$

From the values given in Table 2 it may be calculated that in presence of either 2:4-dinitrophenol (0.1 mM) or dicumarol (0.01 mM), the P/O ratio = 0.26.

Another approach towards this measurement of ineffective or uncoupled respiration is to compare the rates of incorporation of glycine-1-<sup>14</sup>C into the tissue proteins (for such a reaction is well known to be ATP-dependent) in the presence and absence of the uncoupler. It will be seen in the results given in Table 3 that, in the absence of glucose, when glycolytic ATP is not available, the ratio of the rates of incorporation of glycine-1-<sup>14</sup>C, into Ehrlich ascites proteins, in the presence and absence of 0.1 mM dinitrophenol =  $36/146 = 0.25$ . Assuming that this ratio represents the ratio of the rates of formation of ATP in the cell, in the presence and absence of the drug, this value will also express the ratios of the coupled rates of respiration in the cell under the two conditions. As the

$Q_{O_2}$  (in absence of glucose) in absence of the drug = 13.2 (Table 3), the effective or coupled  $Q_{O_2}$  (in absence of glucose) will be  $13.2 \times 0.25 = 3.3$  in presence of the drug. This may be compared with the value of 1.8 already given here, which, however, is the value calculated from experimental results obtained in the presence of glucose.

Calculations of the extent of uncoupling may be made, therefore, either from the ratios of the rates of incorporation of glycine-1- $^{14}C$  into tissue proteins, or from the aerobic and anaerobic glycolytic rates, or on the basis of the conclusion that the sum of the rates of formation of respiratory ATP and glycolytic ATP (in the presence of glucose) is constant. Such calculations show that, in the presence of 0.05 mM and 0.1 mM 2:4-dinitrophenol, the coupled respiratory rates, calculated from the respiratory and aerobic glycolytic rates, are far lower than the observed respiratory rates in presence of glucose, but approximate to the value of the observed respiratory rates calculated from the ratios of the rates of incorporation of glycine-1- $^{14}C$  into the tissue proteins in absence of glucose. For example, from Table 3, the coupled  $Q_{O_2}$  in presence of 0.05 mM dinitrophenol and in absence of

glucose is equal to  $\frac{73 \times 13.2}{146} = 6.6$  when calculated

from glycine incorporation rates and equal to  $\frac{75.2 - 41.2}{6}$

= 5.7 when calculated from the anaerobic and aerobic glycolytic rates. The observed respiratory rate,  $Q_{O_2}$ , is equal to 16.8. Concentrations of 2:4-dinitrophenol higher than 0.1 mM lead to diminutions of respiratory rates. It is evident that other effects of dinitrophenol are operating at relatively high concentrations<sup>4</sup>, the reasons for which are not yet clear and allowance for them cannot be made at present.

Dicumarol acts as a typical uncoupler at the concentrations, 0.005 mM and 0.01 mM, investigated. Again, it is evident from results quoted in Table 3 that the coupled  $Q_{O_2}$  calculated from the aerobic and anaerobic glycolytic rates is far less than the observed respiratory rate in presence of glucose, and approaches the value of the coupled  $Q_{O_2}$  calculated from the values of the glycine incorporation rates into proteins found in the absence of glucose. A similar observation applies to the metal chelator, *p*-nitrobenzene-azo-resorcinol.

Values of incorporation of glycine into tissue proteins in the presence of glucose, aerobically or anaerobically,

show that 2:4-dinitrophenol and dicumarol have negligible inhibitory effects on protein biosynthesis at the concentrations tested (Table 3). *p*-Nitrobenzene-azo-resorcinol acts as an uncoupler without significant effect on total energy metabolism. It seems, however, to exercise an inhibitory effect, that gradually increases with increase of concentration, on anaerobic incorporation of glycine-1- $^{14}C$  into the proteins of Ehrlich ascites tumour cells.

Measurements of respiratory rates, and aerobic and anaerobic glycolytic rates in presence of an inhibitor are obviously helpful in indicating whether the inhibitor is acting mainly as a respiratory uncoupler, respiratory inhibitor or glycolytic inhibitor. Thus it will be seen from the results given in Table 2 that malonate, iodoacetate, carzinophilin, diazouracil and phloretin exercise respiratory or glycolytic inhibitions without any demonstrable uncoupling effects at the concentrations tested.

In summary, the present work shows that, in presence of a variety of metabolic inhibitors which affect the energetics of the Ehrlich ascites cell, the generalization holds that the fall in the rate of formation of ATP by diminished effective respiration, due to the inhibitor, is balanced by an approximately equal rise in the rate of formation of ATP by increased glycolysis. Moreover, the fall in the rate of formation of ATP by a decreased glycolytic rate, due to an appropriate inhibitor, is balanced by a rise in the rate of formation of ATP by increased respiration in the presence of glucose. From a knowledge of the different rates of incorporation of radioactivity from glycine-1- $^{14}C$  into tissue proteins, in the presence or absence of the inhibitor, or from the aerobic and anaerobic glycolytic rates under the same conditions, it is possible to estimate approximately the amount of uncoupling of phosphorylation from oxidation that occurs with inhibitors which act solely as uncouplers and thereby that amount of tumour respiration which is coupled to biosynthetic processes.

## SUBSTRATE EFFECT ON HEAT INACTIVATION OF TAKA-AMYLASE A

By GIITI TOMITA and SAM SOON KIM

Institute of Biophysics, Kyushu University, Fukuoka, Japan

IT is known that some enzymes, for example, D-amino-acid oxidase<sup>1</sup>, glutamic dehydrogenase<sup>2</sup>, lactic dehydrogenase<sup>3</sup>, alcohol dehydrogenase<sup>3</sup>, bacterial  $\alpha$ -amylase<sup>4</sup> and taka- $\alpha$ -amylase<sup>5</sup>, are protected from the inactivation and denaturation by coenzymes or substrates or related compounds. Okunuki and others<sup>4,5</sup> concluded that the protective effect of starch on the inactivation and denaturation of taka- and bacterial  $\alpha$ -amylase by heat, acid and urea must be derived from the hydrolysis products of starch, for the reason that starch was completely hydrolysed within 1 min under experimental conditions. Furthermore, they concluded that the protective effect of digestion products of starch was attributed to protection of the secondary structure of enzyme proteins from denaturation.

This article deals with more detailed protective action of substrate, starch, from heat inactivation in the case of taka-amylase A, and the separation of protective effect

of starch from that of decomposition products from starch was performed under the suitable experimental conditions.

Taka-amylase A is highly protected from heat inactivation by the presence of substrate, starch. This is shown in Fig. 1. Curve (1) shows activity-incubation temperature relation (incubated for 10 min). In the absence of substrate, activity decreases suddenly over 50° C and is completely lost at about 65° C. On the other hand, the presence of substrate (0.6 per cent starch) gives rise to remarkable resistance against heat inactivation, and the activity-incubation temperature curve shifts towards higher incubation temperature than curve (1) as shown in Fig. 1 (2).

The amount of this shift is about 3.5° C under the present experimental conditions, and this is thought to be the 'effective temperature' lowered as substrate effect. Curve (3) is the difference between curve (2) and (1) and shows a sharp peak at about 60° C. From curve (3), it

Fig. 1. Change of activity of taka-amylase A with incubation temperature. Incubation time, 10 min; concentration of taka-amylase A, 0.005 per cent at pH 5.6 (0.2 M acetate buffer). Curve (1), taka-amylase A alone; curve (2), taka-amylase A + starch (0.6 per cent); curve (3), difference of activity between (2) and (1).

is understood that the protective action is most remarkable at the 'transformation temperature' from native to denaturation. Heat inactivation was carried out by the following procedure. Aqueous solutions of taka-amylase A (0.005 per cent), in the absence and presence of 0.6 per cent soluble starch, are incubated for 10 min at various temperatures in the thermostat and rapidly cooled at 0°C after incubation. The activity of taka-amylase A was measured at 40°C by the blue value method<sup>6</sup>. All the experiments were made in 0.2 M acetate buffered solutions at pH 5.6. Taka-amylase A was prepared from 'takadiastase Sankyo' and recrystallized three times from aqueous acetone solution containing 0.01 M calcium acetate by Akabori's method<sup>7</sup>.

Fig. 2 shows the dependence of activity on incubation time at an incubation temperature of 60°C, which is the temperature with the most effective protective action. Curves (1) and (2) show activity-incubation time relation in the absence and presence of substrate respectively. It takes a much longer incubation time in the latter case than in the former to obtain an equal degree of inactivation.

This is shown in curve (4) obtained from the difference between the incubation time in curve (2) and (1) at the same inactivation. From the extrapolation of curve (4) to zero activity, it is known that the longer incubation time in the coexistence system of substrate by about 9 min over that of the substrate-free system is necessary for complete inactivation. Curve (3) shows the difference between the activity in both systems at the same incubation time. The optimum activity is observed after about 9 min

Fig. 2. Change of activity of taka-amylase A with incubation time. Incubation temperature, 60°C; concentration of taka-amylase A, 0.005 per cent, at pH 5.6 (0.2 M acetate buffer). Curve (1), taka-amylase A alone; curve (2), taka-amylase A + starch (0.6 per cent); curve (3), difference of activity between (2) and (1); curve (4), difference of incubation time between (2) and (1).

of incubation. The protective action observed in the presence of substrate is thought to be derived from the superimposed effects of starch and its hydrolysis products. In order to separate the protective effect of starch from that of hydrolysis products, the incubation was made after various periods of digestion. The dependence of activity on digestion time is shown in Fig. 3 (1).

Fig. 3. Changes of activity of taka-amylase A with digestion time before heat treatment and of starch concentration with digestion time, and contributions to protective action from starch and hydrolysis products. Incubation temperature, 59°C; incubation time, 10 min; concentration of taka-amylase A, 0.005 per cent at pH 5.6 (0.2 M acetate buffer). Curve (1), taka-amylase A + starch (0.6 per cent); curve (2), starch concentration at various digestion times; curve (3), protection by starch (degree of polymerization  $> \sim 6$ ); curve (4), protection by hydrolysis products (degree of polymerization  $< \sim 6$ ); \*, \*\*, \*\*\* and § are, respectively, the activity after heat treatment in the presence of dextrin, maltose, glucose and limit dextrin.

The incubation temperature and time are, respectively, 59°C and 10 min, at which the protective action is most remarkable, as shown in Figs. 1 and 2. In the absence of starch, activity decreases to 32 per cent after heat treatment. The amount of substrate (degree of polymerization  $n > \sim 6$ ) in the course of digestion, which was measured by iodostarch reaction, is shown in Fig. 3, curve (2).

As shown in Fig. 4, the decrease in activity by heat treatment is proportional to the concentration of substrate in the region of low substrate concentration, where the incubation temperature and time are, respectively, 60°C and 10 min and incubation was started immediately after mixing the substrate with amylase solution.

This proportionality makes it possible roughly to separate the total protected amount (expressed in activity difference between curve (1) and the activity after heat treatment in the absence of substrate) into two parts: protected amount by substrate ( $n > \sim 6$ ) and that by decomposed compounds ( $n < \sim 6$ ). These are shown in Fig. 3 (3) and (4) respectively. In the short period of digestion, the protection is mainly due to the effect of substrate ( $n > \sim 6$ ). This protective effect is thought to be attributable to the stabilization of the secondary structure of enzyme protein by the formation of enzyme-substrate complex. The formation of an intermediate enzyme-substrate complex in enzyme-catalysed reaction was first postulated by Michaelis and Menten<sup>8</sup>. This concept has been experimentally proved from kinetics of enzyme reactions by various workers, in various systems. Keilin and Mann, and others<sup>9</sup>, have shown spectroscopically the existence of complexes of peroxides with catalase and peroxidase and calculated the thermodynamic quantities of enzyme-substrate complex such as free energy, entropy and enthalpy. Recently, the change of higher order structure of enzyme on the formation of enzyme-substrate complex has been investigated by means of optical rotation<sup>10</sup> and difference spectra<sup>11</sup>.

\* The minimum degree of polymerization of amylose to colour on treatment with iodine. cf. Swanson, M. A., *J. Biol. Chem.*, 172, 825 (1948).

Fig. 4. Dependence of activity after heat treatment on starch concentration. Incubation temperature, 60° C; incubation time, 10 min; concentration of taka-amylase A, 0.005 per cent at pH 5.6 (0.2 M acetate buffer)

These experimental results show that the structure of enzyme protein changes from disorder to order on the formation of enzyme-substrate complex. Such a structural change may lead to stabilization of the enzyme and to protection from external disturbances, for example by heat treatment. On heat inactivation of taka-amylase A, the presence of substrate seems greatly to stabilize the secondary structure of enzyme protein by the formation of enzyme-substrate complex and to give rise to a profound resistance against inactivation and denaturation. A difference spectrum of taka-amylase on the formation of complex with substrate has not been observed, but in the cases of lysozyme and  $\alpha$ -chymotrypsin<sup>11</sup>, difference spectra on the formation of enzyme-substrate complex are well established. On the formation of enzyme-substrate complex, ultra-violet absorption spectra of enzymes usually show 'red shift' and this means the conformation change of enzyme protein from disorder to

order. This conformation change may conjugate with the appearance of enzyme activity. The ordered and rigid structure of enzyme protein may be essentially responsible for the appearance of enzyme activity. Furthermore, this structure may be highly stabilized and protected from the external disturbance such as thermal agitation. This seems to be the main reason why taka-amylase can be protected from heat inactivation by the presence of substrate. The decomposition products from starch,  $\alpha$ -limit dextrin and maltose are also effective for protection of amylase from heat inactivation, but glucose has no protective effect. In the presence of these substances (0.6 per cent in each), the activity decreases by heat treatment (at 59° C and for 10 min) to 38, 37 and 32 per cent respectively, as shown in Fig. 3. Limit dextrin and maltose seem to stabilize the secondary structure by combination with amylase, and to protect it from heat inactivation and denaturation, though the effect is not so great. The site with which these compounds are combined, unlike substrates, is not necessarily the active point of amylase. So, the induced stabilization is considered to be probably similar to that by calcium ions<sup>12</sup>.

## REPRESSION OF GROWTH, AND SUBSEQUENT ADAPTATION, OF A PARENTAL STRAIN TUMOUR IN GENETICALLY COMPATIBLE $F_1$ HYBRID MICE

By DR. RICHARD P. HUEMER

Division of Biology, California Institute of Technology, Pasadena

AS is known from the work of many investigators<sup>1</sup>, starting with C. C. Little, the successful transplantation of neoplasms, as of normal tissues, depends on their not possessing histocompatibility antigens different from those of the host. Thus, transplantation generally succeeds within inbred lines of animals or from animals of an inbred line to  $F_1$  hybrids between that inbred line and some other (not necessarily inbred) line.

However, recently a number of investigators<sup>2-5</sup> have reported experiments in which a tumour growing in a particular inbred line of mice grows less readily, or not at all, in  $F_1$  hybrid hosts. A comparable phenomenon of deficient growth of normal parental bone marrow cells in the  $F_1$  has also been reported<sup>6,7</sup>. The purpose of this article is to report a similar  $F_1$  hybrid effect with a transplantable tumour and, in addition, an adaptive change in the tumour.

Female mice of the A/J and C57BL/6J strains, and their  $F_1$  hybrid ( $B_6A.F_1$ ) (designated as A, B and  $F_1$ , respectively), were used. A suspension of lymphoma, minced with not more than 0.25 volume of physiological saline, was injected through a 16-gauge needle into the sub-

cutaneous tissues of the neck-and-shoulders region. The lymphoma had originated in a B mouse near the site at which syngeneic spleen fragments had been injected 97 days previously in connexion with other experiments<sup>8</sup>.

The primary tumour was transplanted after 28 days into 4 A, 4 B and 4  $F_1$  mice, and grew progressively only in 2 of the B hosts. In one (designated 21) the tumour developed more slowly than in the other (21a). Tumour 21a was transplanted (0.4-0.8 ml. of suspension) after 71 days into 5  $F_1$  and 3 B hosts, two of the latter having previously rejected the original tumour. It failed to grow progressively in the rejectors and  $F_1$  hybrids, but grew to large size in one B host. On days 198 and 127, respectively, after the previous transfers, a second transplantation with a single tumour of line 21 and a third with a single tumour of line 21a were made, 0.2 ml. of suspension of each tumour having been injected into six animals of each of the three genotypes. The results are shown in Table 1.

Histological examinations of specimens removed from all 18 tumour-bearing mice failed to reveal any obvious

Fig. 1. Cumulative mortality (percentage of tumour-bearing mice having died with tumours) in  $B$  and  $F_1$  groups, exclusive of resistant  $F_1$ s.

differences in appearance between lines 21 and 21a, and between tumours grown in  $B$  or  $F_1$  hosts.

One  $B$  and one  $F_1$  recipient of tumour 21 were killed, as indicated in Table 1, in order to transplant their tumours which weighed, respectively, 6.96 g (21B tumour) and 11.18 g (21BF tumour) exclusive of metastases. The 21B tumour was transplanted (0.2 ml. of suspension) to 7 stock  $B$ , 7 stock  $F_1$ , and 7 'resistant'  $F_1$  that had rejected previous grafts of the original tumour or its sublines 21 and 21a. Likewise, the 21BF tumour was transferred to 6 stock  $B$ , 7 stock  $F_1$  and 7 'resistant'  $F_1$ . The results are shown in Table 2 and Fig. 1. In Table 2, persisting tumours are those which were present until the death of the animal or until the termination of the 25-week observation period; regressing tumours were present at some time after the second week but were not present at the end of 25 weeks or when the animal died.

Table 1. BEHAVIOUR OF TWO TRANSPLANTABLE LYMPHOMAS OF COMMON ORIGIN IN HOMOZYGOUS AND  $F_1$  HYBRID HOSTS

Tumour	Hosts	No. in group	No. with tumours	Days post-grafting on which deaths occurred
21	$B$	6	6	56, 64, 75, 78, 81
	$F_1$	6	1	(one killed on day 82)
	$A$	6	0	(one killed on day 87)
21a	$B$	6	6	56, 60, 60, 62, 71, 73
	$F_1$	6	5	(All 5 killed on day 85)
	$A$	6	0	—

Table 2. RESULTS OF TRANSPLANTATION EXPERIMENTS WITH  $F_1$ -PASSED (21BF) AND UNADAPTED (21B) TUMOURS

Tumour	Type of host	No. of mice in group	No. with persisting tumours	No. with regressing tumours	No. dying with tumours	Survivors through 25th week
21BF	$B$	6	6	0	6	0
	$F_1$	7	6	0	6	0
	Resistant $F_1$	7	3	3	3	4
21B	$B$	7	6	0	6	1
	$F_1$	7	6	0	2	5*
	Resistant $F_1$	7	1	5	1	5

\* Four bearing tumours. These died during the 28th, 35th, 37th and 48th weeks.

The 21B tumour, which had never been exposed to the  $F_1$  environment, exhibited deficient growth in the  $F_1$  hosts, whereas the 21BF tumour, which had been passed through an  $F_1$  host, behaved toward ordinary  $F_1$  hosts as it did toward syngeneic  $B$ -hosts. Of the resistant  $F_1$  hosts, a greater proportion survived challenge with the 21B tumour than with the 21BF tumour, and there were more cases of tumour regression among resistant  $F_1$  recipients of  $B$  tumour.

(The sixth transplant-generation of the 21B tumour was grown in 9  $B$  and 9  $B_6D_3F_1$  hosts. Deficient growth of the tumour in  $F_1$  hosts was again observed.)

It is known that tumours occasionally undergo alterations that permit them to grow in a greater percentage of  $F_1$  hybrid hosts or hosts produced by back-crossing  $F_1$  hybrids to the resistant parental strain<sup>9</sup>, and these changes are generally regarded as being due to loss or inactivation of isoantigenic determinants within the tumour cells, permitting the cells to avoid provoking the homograft-rejection reaction in foreign hosts<sup>10-14</sup>. The methods by which tumours may be adapted to foreign hosts include

passage through adult<sup>11</sup> and embryonic<sup>13</sup> foreign genotypes, through radiation chimaeras<sup>14</sup> and through half-foreign  $F_1$  hybrids<sup>15,16</sup>. In the latter experiments<sup>15,16</sup> the  $F_1$ -passed tumours grew in a greater proportion of resistant back-cross mice and thus behaved as though exposure to the  $F_1$  environment had caused them to lose certain isoantigens.

Snell and Stevens<sup>9</sup> suggested that the deficient growth of parental tumours in  $F_1$  hybrids might be due to an abortive graft-versus-host reaction. Presumably the mechanism for this might be allergic death of the grafted cells<sup>17</sup>. Hellström<sup>8</sup> argues against abortive graft-versus-host reaction inasmuch as the effect is obtained with grafts of

tissues that are presumably not immunologically competent. This argument presupposes that the relevant tumours or their normal counterparts do not possess cells that are immunologically competent or capable of becoming so<sup>8,18</sup>. However, without referring specifically to allergic death, Hellström<sup>8</sup> suggested that exposure to foreign antigens of the host may inhibit the growth of transplanted cells. He<sup>4</sup> also considered the possibility of recessive histocompatibility ( $H$ ) genes, but argued against this because: (1) recessiveness of  $H$ -genes has not been unequivocally demonstrated in various experiments; (2) irradiation of the  $F_1$  hybrid prior to grafting does not abrogate its relative resistance.

For the similar phenomenon with normal bone marrow, Cudkovic and Stimpfling<sup>6</sup> offer modifications of the recessive  $H$ -gene and allergic-death hypotheses, and favour the view that, in heterozygotes, interallelic interaction prevents or modifies the expression of a genetic determinant in the  $H$ -2 locus "whose expression is required for the growth of transplanted marrow cells". The unimpaired growth of transplanted marrow cells in allogeneic homozygous hosts is considered<sup>6</sup> to be opposed to the allergic-death interpretation.

Since the present findings of preferential growth of the tumour in the parental strain of origin are similar to those of the authors previously cited<sup>2-7</sup>, they are subject to similar interpretations; but the additional phenomenon of adaptive change would tend to favour explanations based on selection of genetic variant cells. If one or more parental isoantigens were not expressed on cell-surface sites in the  $F_1$  hybrid, then the deficient growth of the 21B tumour in the  $F_1$  hybrids initially could be due to an  $F_1$ -antiparent immunological reaction, conditioned by the  $H$ -genes of that parent being recessive in the  $F_1$ . The unimpaired growth in the  $F_1$  of the 21BF tumour in later transplant generations could be interpreted as due to an antigenic simplification of the tumour, the lost isoantigens being those that are non-codominant. If it is assumed that the proliferative stimulus to the tumour is greater the greater the number of host antigens that it lacks<sup>6,18</sup>, then selection would operate in the direction of such antigenic simplification. This would also permit growth in a greater percentage of resistant back-cross animals, as has been described<sup>15,16</sup>.  $F_1$  serum factors would in this case be effective as additional selective agents in conditioning—or enhancing—the parental tumour<sup>19</sup>, as antisera are known to be<sup>9</sup>. The results presented here are also consistent with the allergic-death explanation on the assumption that exposure to the  $F_1$  hybrid environment has selected a population of parental-strain tumour cells which are resistant to such destruction. A third possibility, consistent with the present results and that of the other authors, is that a naturally occurring autoantibody, perhaps possessing normally a growth-regulating function, is expressed more completely in heterozygotes and is capable of inhibiting the growth of homozygous cells<sup>20</sup>. The homozygous cells would adapt to its presence through suppressed production of isoantigens.

## GLUCOSE METABOLISM VIA THE PENTOSE PHOSPHATE PATHWAY RELATIVE TO CELL REPLICATION AND IMMUNOLOGICAL RESPONSE

By PROF. PETER BEACONSFIELD\*, DR. JEAN GINSBURG and Z. KOSINSKI†

Wellcome Laboratories, Department of Obstetrics and Gynaecology, Charing Cross Hospital Medical School, London, W.C.2

**R**EGULATION of glucose metabolism via the pentose phosphate pathway by pharmacological agents may provide a means of influencing cell replication and protein production.

The metabolism of glucose via the pentose route produces pentose sugars, the necessary building blocks for the biosynthesis of RNA and DNA, and, in turn, for protein formation. Thus inhibition—whether physiological or biochemical—of glucose utilization via the pentose cycle will result in a reduced production of D-ribosyl units and consequently diminish certain cellular function such as that of replication and the formation of proteins.

*In vitro* experiments have demonstrated a parallelism between the rate of pentose shunt activity and that of RNA synthesis in normal tissue<sup>1</sup>, and the rate of pentose shunt activity and that of RNA and DNA synthesis in malignant tissue<sup>2</sup>. It has also been established that a decrease in glucose metabolism via the pentose route, whether due to normal physiological response<sup>3</sup> or to the effects of chemical compounds<sup>1,2</sup>, entrains simultaneous corresponding repercussions in cell processes requiring nucleic acid and protein synthesis.

Thus, while there is consistently clear evidence of a parallelism between the rate of pentose shunt activity, nucleic acid synthesis and protein production in both normal and malignant tissues, definite confirmation has been lacking as to whether alterations in the rate of pentose shunt activity directly induce corresponding fluctuations in the formation of pentose sugars.

Such evidence was sought by isolating and identifying the amount of pentose sugars in the RNA and estimating its turn-over rate relative to that of pentose shunt activity and total RNA synthesis.

Three types of tissue were examined: human placenta during the first trimester of pregnancy and at term, normal and regenerating rat liver and adenocarcinoma of the large bowel.

The tissue samples were cut with a Stadie-Riggs slicer into thin slices weighing about 100 mg which were transferred to Warburg flasks containing ice-chilled Krebs-Ringer bicarbonate buffer medium at pH 7.4 with a

glucose concentration of 0.15 per cent. The samples were incubated for 150 min at 37° C in 95 per cent oxygen and 5 per cent carbon dioxide. Four types of radioactive material were used in this investigation: U-<sup>14</sup>C glucose, glucose-1-<sup>14</sup>C, glucose-6-<sup>14</sup>C and U-<sup>14</sup>C glycine.

The specific activity of nucleic acid and ribose turnover was measured by their incorporation of U-<sup>14</sup>C glucose. The RNA was isolated from the homogenized tissue by Kirby's phenol method<sup>4</sup> and recovered from the two-phase partition system as a cetyltrimethyl ammonium salt<sup>5</sup>. Approximately a half of the RNA sample was used to determine the total radioactivity; the other aliquot was hydrolysed with 1 N hydrochloric acid for 1 h at 100° C, after which the hydrolysate was run on Whatman No. 3 paper in a system of *n*-butanol (50 vol.), pyridine (30 vol.) and water (20 vol.). The positions of the pyrimidine and purine bases were located by ultra-violet examination of the chromatogram, and the positions of the ribose and glucose were determined by spraying the chromatogram with aniline oxalate and developing it at 100° C dry heat for 10–20 min. Glucose appeared as a brown spot and ribose as a pink one. Originally, the radioactivity was measured by an automatic chromatographic scanner, but because of the relatively low counts obtained this was consequently done in a liquid scintillation counter.

To some flasks, for each 3 ml. of incubating medium, was added a TPNH generating system which depresses the activity of the shunt<sup>1</sup>. In our experiments, this system comprised 0.1 ml. of 10 per cent ethanol containing 150 µg of crystalline alcohol dehydrogenase (ADH). To other flasks was added 0.2 ml. of 0.05 per cent methylene blue per 3 ml. of incubating medium, this being an electron accelerator which increases the metabolism of glucose via the pentose phosphate pathway.

To minimize the often varied effects of ethanol alone on tissue metabolism obtained in previous investigations<sup>1</sup> the concentration in the present series of experiments represents one-fifteenth of that previously used. In this concentration, ethanol alone produced practically no alteration in the rate of glucose metabolism via the pentose cycle; yet when the ADH was added the desired depressant effect was constant and always reproducible.

The relative utilization of the pentose phosphate pathway in glucose metabolism was determined on the basis

\* Precursor U-<sup>14</sup>C glucose. † Precursor U-<sup>14</sup>C glycine.

of the fractional recoveries of carbon dioxide from glucose-1-<sup>14</sup>C and glucose-6-<sup>14</sup>C, and also by measuring the amount of radioactive material in the medium before and after incubation. Protein production was determined by the rate of incorporation of U-<sup>14</sup>C glycine into total protein.

All tissues examined showed that, in the presence of ADH, pentose shunt activity was decreased, the carbon dioxide yields from glucose-1-<sup>14</sup>C being reduced by at least 30 per cent, while those from glucose-6-<sup>14</sup>C remained virtually unchanged. This reduction was also borne out by calculating the amount of radioactive glucose utilized during incubation. Methylene blue, on the other hand, greatly increased the rate of glucose metabolism via the pentose phosphate route, the carbon dioxide yield from glucose-1-<sup>14</sup>C often being doubled. These findings are in accord with data already obtained in previous investigations<sup>1,2</sup>.

The incorporation of U-<sup>14</sup>C glucose into RNA and its ribose fraction are shown in Table 1. Term placenta reveals an RNA value about one-third of that present during the first trimester of pregnancy. This is in accord with the observation<sup>3</sup> that in the first trimester of pregnancy the rapidly growing placenta demonstrates a high rate of glucose metabolism via the pentose phosphate pathway; whereas, at term, the utilization of this pathway is so much reduced as to be almost immeasurable. After hydrolysis and subsequent chromatography, some 80 per cent of the total RNA count was found to be concentrated in ribose and pyrimidine spots. The former comprised 10–20 per cent of the total radioactivity measured and this proportion of ribose corresponded in all tissues examined with the RNA turnover and the rate of pentose shunt activity, whether the latter was influenced by physiological or pathological processes, or the addition of ADH to the medium.

Normal and regenerating liver revealed a similar picture to placenta inasmuch as the regenerating liver, being an actively growing tissue, has an increased pentose shunt activity with correspondingly increased D-ribose formation and nucleic acid synthesis.

In all the experiments using placenta, liver and adenocarcinoma of the bowel, the presence of ethanol ADH in the medium during incubation of the tissue reveals a decreased ribose formation and nucleic acid synthesis consequent to the decreased rate of pentose shunt activity.

In all instances, the decrease in pentose shunt activity—whether produced by physiological or pharmacological means—was followed by a reduction in ribose formation and nucleic acid synthesis. The addition of the electron accelerator to the medium, while always producing a marked elevation in glucose metabolism via the pentose route, did not entrain a parallel augmentation in ribose and RNA formation, these revealing only a slight increase.

A rise in pentose shunt activity will produce a corresponding simultaneous increase in ribose formation and RNA synthesis only in response to physiological or pathological demands *in vivo* where the other necessary intermediate products become available in the elevated quantities required. *In vitro*, this cannot be accomplished by increasing the pentose shunt alone.

Alternatively, a decrease in glucose metabolism via the pentose route will always entrain parallel reduction in the formation of ribose and nucleic acids, as a decreased availability of any one of the compounds essential for the synthesis of nucleic acids will limit their formation.

Timed experiments and others still in progress suggest that the reduction in pyrimidine and purine bases (Table 1) can be considered, in the main, as secondary to a decrease in ribose formation. Furthermore, the metabolic effects of ethanol-ADH may involve some action additional to that on the TPNH generating system.

In all types of tissue examined, reduction in glucose metabolism via the pentose phosphate pathway is also concurrent—as can be seen from Table 1—with a decrease in protein formation. This is probably mainly a repercussion of reduced RNA synthesis, since it is now believed that the rate of protein production is dependent on the availability of messenger RNA<sup>6</sup>. Thus, the effects on general protein biosynthesis of alterations in the rate of pentose shunt activity can be considered secondary to the primary effects on nucleic acid formation.

Antigenic stimulation producing antibodies is essentially a process involving protein (γ-globulin) formation. Investigations of antibody formation in rabbit spleen show that initiation of the immunological response is characterized by increased glucose metabolism via the pentose cycle with augmented ribose formation and, thus, nucleic acid synthesis.

The results of the investigation recorded here therefore illustrate that: (a) ribose formation runs in parallel with the rate of glucose metabolism via the pentose phosphate pathway; (b) if the rate of glucose metabolism via the pentose phosphate pathway is altered by physiological or pharmacological means simultaneous changes are produced in the rate of D-ribose formation and consequently in RNA synthesis and protein production.

It can thus be stated that a prolonged reduction in pentose shunt activity with the concomitant decrease in nucleic acid synthesis should incur repression of cell replication and interference with some aspects of immunological reaction.

## ANALYSIS OF FOVEAL DENSITOMETRY

By PROF. H. RIPPS and DR. R. A. WEALE

Department of Ophthalmology, New York University Medical Center,  
New York, and Department of Physiological Optics, Institute of  
Ophthalmology, Judd Street, London, W.C.1

THE identification and analysis of the visual pigments *in situ* are based on fundamental principles of spectrophotometry. Moreover, they involve those factors which are unique to the physico-chemical organization of the pigment molecules within the receptors and the spatial distribution and orientation of these elements within the retina. Spectral densitometry of a light-absorbing medium relates the wave-length of the incident radiation to the attenuation of said radiation by absorption on passage through the medium. The interpretation of densitometric data is greatly simplified in the usual circumstance of measurement where the pigment molecules are distributed uniformly throughout their container and the Beer-Lambert laws are directly applicable. If these conditions are satisfied, then the optical density of a mixture of solutes is given by the sum of the component densities. The situation becomes more complicated when the molecules are not distributed uniformly in space.

For purposes of this article one can distinguish two special cases: (a) the existence of concentration gradients or boundaries in planes perpendicular to the direction of the light beam utilized for transmissivity measurements (Fig. 1a); (b) occurrence of such gradients or boundaries in planes parallel to the measuring beam (Fig. 1b).

Both these conditions are represented in the organization of pigments within the receptor layer of the retina (Fig. 1c). It is the object of this article to compare densitometry for these two conditions, to illustrate how each obtains as regards the quantitative analysis of visual pigments, and to examine some predictions derived from this analysis in the light of experimental measurements on the human retina.

**Theory.** The laws of Beer and Lambert state that the optical density  $D_\lambda$  (defined as the negative common logarithm of the spectral transmission factor  $T_\lambda$ ) is proportional to the concentration  $c$  of the medium and the path-length  $x$  of the light therein:

$$D_\lambda = -\log_{10} T_\lambda = \alpha_\lambda c x \quad (1)$$

where  $\alpha_\lambda$ , the extinction coefficient, is determined by the molecular configuration of the medium and is a function of the wave-length of the measuring light.

It is readily seen that if there is more than one light-absorbing substance ordered in the form of layers perpendicular to the test beam (Fig. 1a), the total density is equal to the sum of the component densities. The fraction of light transmitted by layer 1 is  $T_1$ , that by layer 2 is  $T_2$ , and so on. The total fraction of the incident light transmitted  $T_{\text{total}}$  is given by:

$$T_{\text{total}} = T_1 \cdot T_2 \cdot T_3 \cdot \dots \cdot T_n \quad (2)$$

or, from equation (1):

$$D_{\text{total}} = D_1 + D_2 + D_3 + \dots + D_n \quad (3)$$

In this result the individual layers have lost their identity, and it follows that this is equivalent to the situation of uniformly mixed solutes cited previously. In particular, if a given single type of pigment is arranged in laminae, such an ordered distribution would not appear to affect the issue, provided one recognizes that the longitudinal dimension of the container does not represent the optical path length  $x$ . Merely from the point of view of the operation of Lambert's law, the laminar arrangement of the visual pigments in the retinal receptors<sup>1</sup> would

seem to be wasteful of available space. We have to remember, however, that for a given number of pigment molecules contained in a tube of fixed cross-sectional area, the optical density is proportional to the product  $\alpha c x$ . The particular merit of the lamellar organization of the visual pigment molecules is that, owing to their intrinsic three-dimensional asymmetry, their chances of capturing light quanta is appreciably enhanced<sup>2</sup> (but compare Weale<sup>3</sup>).

What would be the effect of such gaps on densitometry if they were parallel rather than perpendicular to the light beam (Fig. 1b)? Let us assume that we are still dealing with only one type of pigment, and that it is contained in tubules parallel to the incident light  $I_{\text{inc}}$ . Let the cross-sectional area of the light beam be unity and the total fractional cross-sectional area of the tubules be  $A$ , where  $A < 1$ . The light transmitted by the array will thus consist of two components: (a) one which has passed unattenuated through the gaps, and (b) the other reduced by absorption in the pigment. The measured transmissivity  $T_m$  is given by:

$$T_m = \frac{I_{\text{trans}}}{I_{\text{inc}}} = \frac{I_{\text{inc}}(1-A) + I_{\text{inc}} \cdot A \cdot T_p}{I_{\text{inc}}} \quad (4)$$

where  $T_p$  is the transmission factor of the pigment. Equation (4) reduces to:

$$T_m = (1-A) + A \cdot T_p \quad (5)$$

It is apparent that no matter how small  $T_p$ , if the pigment occupies only a small part of the measuring area its presence may go undetected. As densitometrists know, isolated specks of dust are mercifully without much effect on their results.

Suppose now that the above-mentioned array consists of  $n$  tubules of cross-sectional area  $A_{1-n}$ , each containing a pigment of transmission factor  $T_{1-n}$ . Furthermore, let there be inter-tubular spaces the total area of which is equal to  $1 - \sum_{i=1}^{i=n} A_i$ . Then the transmitted light  $I_{\text{trans}}$  is made up of the components:

$$I \cdot A_1 \cdot T_1 + I \cdot A_2 \cdot T_2 + I \cdot A_3 \cdot T_3 + \dots + I \cdot A_n \cdot T_n + I \left[ 1 - \sum_{i=1}^{i=n} A_i \right]$$

and the measured transmissivity is:

$$T_m = A_1 \cdot T_1 + A_2 \cdot T_2 + A_3 \cdot T_3 + \dots + A_n \cdot T_n + 1 - \sum_{i=1}^{i=n} A_i \quad (6)$$

Expressed in densities, equation (6) becomes:

$$D_{\text{measured}} = -\log_{10} \left[ A_1 \cdot 10^{-D_1} + A_2 \cdot 10^{-D_2} + A_3 \cdot 10^{-D_3} + \dots + A_n \cdot 10^{-D_n} + 1 - \sum_{i=1}^{i=n} A_i \right] \quad (7)$$

*Application to measurements in the living human eye.* A knowledge of the spectral properties of the visual pigments is of paramount importance to an understanding of many visual functions. But, owing to the presence of light-absorbing pigments other than those subserving vision (for example, blood, pigment epithelium), direct measurements of their transmission factors are unobtainable in

the living eye. One can, however, utilize the photolabile character of the visual pigments to detect and measure the changes in their transmission spectra that result from exposure to light, that is, bleaching. Within limits to be discussed below, such density difference spectra are independent of extraneous absorption or light-scatter. The cardinal point in this regard is that any measurement of density changes in the intact retina involves not equation (7) but the difference between two such equations. This density difference arises from the change effected in one or more of the values  $D_{i\lambda}$  by exposure to light of intensity  $I_\beta$ , where  $\lambda$  and  $\beta$  refer to the wave-lengths of the measuring and bleaching lights, respectively. If  $D_{i\lambda}$  represents the maximum receptor density of a pigment (that is, after complete dark-adaptation), and if it be assumed that following exposure to the bleaching light the receptor density is reduced to  $d_{i\lambda}$ , then the measured density difference  $\Delta D_\lambda$  for pigments  $i=1$  to  $n$  occupying areas  $A_{i=1}$  to  $A_{i=n}$ , respectively, is:

$$\Delta D_\lambda = \log_{10} \left[ \frac{A_1 \cdot 10^{-d_{1\lambda}} + A_2 \cdot 10^{-d_{2\lambda}} + A_3 \cdot 10^{-d_{3\lambda}} + \dots + A_n \cdot 10^{-d_{n\lambda}} + 1 - \sum_{i=1}^{i=n} A_i}{A_1 \cdot 10^{-D_{1\lambda}} + A_2 \cdot 10^{-D_{2\lambda}} + A_3 \cdot 10^{-D_{3\lambda}} + \dots + A_n \cdot 10^{-D_{n\lambda}} + 1 - \sum_{i=1}^{i=n} A_i} \right] \quad (8)$$

The situation is further complicated by the presence of products of the primary bleaching process<sup>5</sup>, and also by the regeneration of the original pigment. Both these factors tend, in general, to diminish the differences between  $D_{i\lambda}$  and  $d_{i\lambda}$  although to different degrees and depending on the value of  $\lambda$ . However, if it be permissible to neglect both regeneration and the effects of the products that arise from quantum absorption (compare Williams<sup>6</sup>), then  $D_{i\lambda}$  and  $d_{i\lambda}$  are related to the energy of the bleaching light by the expression:

$$d_{i\lambda} = D_{i\lambda} e^{-\alpha_i \beta \gamma I_\beta t} \quad (9)$$

where  $\alpha_\beta$  is the extinction coefficient of pigment  $i$  for the bleaching light;  $\gamma$  is the quantum efficiency, defined as the number of visual pigment molecules bleached per number of quanta absorbed; and  $I_\beta$  and  $t$  are the bleaching intensity and time of exposure respectively. Substitution of equation (9) in equation (8) gives:

$$\Delta D_\lambda = \log_{10} \left[ \frac{A_1 \cdot 10^{-D_{1\lambda}} \exp(-\alpha_1 \beta \gamma I_\beta t) + A_2 \cdot 10^{-D_{2\lambda}} \exp(-\alpha_2 \beta \gamma I_\beta t) + A_3 \cdot 10^{-D_{3\lambda}} \exp(-\alpha_3 \beta \gamma I_\beta t) + \dots + A_n \cdot 10^{-D_{n\lambda}} \exp(-\alpha_n \beta \gamma I_\beta t) + 1 - \sum_{i=1}^{i=n} A_i}{A_1 \cdot 10^{-D_{1\lambda}} + A_2 \cdot 10^{-D_{2\lambda}} + A_3 \cdot 10^{-D_{3\lambda}} + \dots + A_n \cdot 10^{-D_{n\lambda}} + 1 - \sum_{i=1}^{i=n} A_i} \right] \quad (10)$$

which may be written:

$$\Delta D_\lambda = \log_{10} \left\{ \frac{1 - \sum_{i=1}^{i=n} A_i [1 - 10^{-D_{i\lambda}} \exp(-\alpha_i \beta \gamma I_\beta t)]}{1 - \sum_{i=1}^{i=n} A_i (1 - 10^{-D_{i\lambda}})} \right\}$$

This equation underlies the measurement of difference spectra in an array of tubules containing various light-sensitive substances, the axes of the tubules being parallel to the light of the densitometer.

We propose to test equation (10) in two ways. First, we wish to determine how  $\Delta D_\lambda$  varies with  $I_\beta$  and compare

Fig. 1. Schematic representation of pigments located in containers with discontinuities (a) perpendicular, and (b) parallel to the direction of the measuring light. (c) The situation as it obtains in the retina (for details see text)

computed values with those observed in the living eye. Secondly, we should like to see to what extent the theoretical analysis predicts variations in the shape of the difference spectra obtained by partial bleaching of cone pigments in the human fovea. In addition, since equation (10) affords a means of estimating the *in situ* pigment densities, it is possible to compare density changes measured in the living eye with those recorded for individual receptors.

**Intensity function.** In the human periphery, where rods dominate the scene and the bleaching of cone pigments does not greatly affect the density difference measurements (but compare Weale<sup>7</sup>), equation (10) may be simplified by setting  $A_{2-n}$  equal to zero. An analysis of the relevant data would, however, lead outside the scope of this article, primarily concerned with cones. The trichromatic theory postulates the existence of three independent colour-mediating mechanisms in the fovea, populated exclusively by cones. If each is subserved by a specific cone pigment housed in separate containers, then solution of equation (10) requires a knowledge of the receptor densities of these pigments for the wave-length of measurement, their photosensitivities ( $\alpha_i \gamma$ ) to the bleaching light, and their respective distributions within the measuring area. Although there are several quantities in the right-hand side of equation (10) which cannot be precisely specified, it is possible to make reasonable estimates of their values based on the spectral characteristics of the foveal pigments determined experimentally and known anatomical features of this region.

It appears, both from reflexion measurements on the living eye<sup>8,9</sup> and microspectrophotometry of foveal sections<sup>10</sup>, that the foveal difference spectrum on total bleaching results principally from the density changes of two photolabile substances: the red-sensitive erythrolabe and the green-sensitive chlorolabe. The blue-sensitive pigment contributes little to the measurements for  $\lambda > 500 \text{ m}\mu$ <sup>10,11</sup>. For the purposes of the computations, therefore, the blue-sensitive pigment can be considered a photostable substance. Now, as regards the remaining pigments, Rushton<sup>8</sup> has indicated that the maximum density change recorded for erythrolabe ( $\lambda_{\text{max}} = 590 \text{ m}\mu$ ) is about 1.5 times that of chlorolabe ( $\lambda_{\text{max}} = 540 \text{ m}\mu$ ), and Brown and Wald<sup>10</sup> have confirmed on isolated retinas that the measured densities are in this ratio (although the  $\lambda_{\text{max}}$  of the

erythrolabe difference spectrum is said to be at a somewhat shorter wave-length; see following). As  $D_{\lambda} = \alpha_{\lambda} c x$ , this finding could result, for example, from either the concentrations or the extinction coefficients of erythrolabe being 1.5 times that of chlorolabe (for equal path lengths  $x$  and fractional areas  $A$ ). Let us assume arbitrarily that the extinction coefficients differ and the concentrations are equal. Then, for equal quantum efficiencies, the relative photosensitivities are as shown in Fig. 2, where the maximum of the P.540 curve is two-thirds that of P.590. The curves of Fig. 2 enable one to read off the relative densities  $D_{\lambda}$  of the two pigments at any measuring wave-length  $\lambda$ , and their relative photosensitivities ( $\alpha_{\beta}\gamma$ ) to any bleaching wave-length  $\beta$ . Thus, for a measuring wave-length  $\lambda = 540 \text{ m}\mu$ , and bleaching with  $\beta = 540 \text{ m}\mu$ ,  $D_{2\lambda}$  (the receptor density of erythrolabe) is taken to be equal to that of  $D_{1\lambda}$  (the density of chlorolabe), and  $\alpha_{1\beta}\gamma_1 = \alpha_{2\beta}\gamma_2$ . Similarly, for  $\lambda = 590 \text{ m}\mu$ ,  $\beta = 540 \text{ m}\mu$ , the photosensitivities are again equal, but  $D_{2\lambda} = 3.57 D_{1\lambda}$ . The expected values of  $\Delta D_{\lambda}$  can now be calculated as a function of  $I_{\beta}$  for various *in situ* pigment densities  $D_{1\lambda}$  and different fractional areas of pigment. It may be mentioned parenthetically that if the opposite assumption be made, namely equal photosensitivities but differing concentrations, the predicted values do not differ greatly from those given below.

Fig. 2. The relative photosensitivities of chlorolabe (P. 540) and erythrolabe (P. 590), plotted on the assumption that density spectra are identifiable with density difference spectra (after ref. 8) and that the quantum efficiencies of the two substances are equal

If we assume that, owing to the close packing of cones within the fovea, chlorolabe, erythrolabe and photo-stable substances each occupy one-third of the total area, then solutions of equation (10) give the results shown in Fig. 3. The values of  $\Delta D(2)$  are for double transit through the retina in order to be compatible with *in vivo* measurements. It will be noted that, irrespective of the assumed values of  $D_{1\lambda}$  (the receptor density of chlorolabe), equation (10) predicts that measurable bleaching occurs over a range of merely 2 log units in intensity—a rather small range as compared with the billion-fold intensity gamut over which the eye responds before experiencing thermal injury. But the prediction agrees with the experimental data (Fig. 4) and is, in fact, similar to what one observes in connexion with rods<sup>12</sup>. If we next plot the experimental results for  $\lambda = 540$  and  $590 \text{ m}\mu$ , taken from the lower graph of Fig. 4, within the framework of predicted values (data points of Fig. 3), a maximum receptor density of about 0.15 for chlorolabe seems to be indicated. The corresponding density computed for erythrolabe is approximately 0.22.

**A spectral shift.** The experimental results of Fig. 4a show that with green bleaching light ( $\beta = 547 \text{ m}\mu$ ) the shapes of the difference spectra were, for measuring wave-lengths  $\lambda > 500 \text{ m}\mu$ , virtually independent of the illuminance of the bleaching light. Although  $\Delta D_{\lambda}$  increased as  $\beta$  was raised, the maxima of the difference spectra ( $\lambda_{\max}$ ) remained at approximately  $560 \text{ m}\mu$ . But bleaching with deep red light produced quite different results (Fig. 4b). Clearly, the curves no longer retain the same shape or position irrespective of bleaching intensity. For the

lowest values of  $I_{\text{red}}$ , the maximal density change occurred at about  $590 \text{ m}\mu$ . As the intensity was raised the  $\lambda_{\max}$  moved to shorter wave-lengths, and, for the highest intensity used, was at approximately  $560 \text{ m}\mu$ . These findings suggest that, whereas green light bleaches the red- and green-sensitive pigments in the same proportion for all intensities, the weak red light bleaches largely the red-sensitive pigment; as the red-sensitive pigment becomes exhausted increasing the intensity increases the proportion of green-sensitive pigment bleached<sup>11</sup>.

To what extent are the constancy of the shape of the difference spectra for green bleaches and its alteration with red bleaches predicted by equation (10)? It is readily seen that a shift in  $\lambda_{\max}$  carries with it a change in the ratio of the density changes obtained at two measuring wave-lengths. For example, in the case of a series of symmetrical curves—as is represented by the green bleaching data—the ratio  $\Delta D_{590}/\Delta D_{540}$  remains constant at all bleaching intensities. But a reduction in this ratio as the bleaching intensity is raised betokens a shift of  $\lambda_{\max}$  toward shorter wave-lengths. Now, from curves such as those of Fig. 3, which give the computed density changes at the measuring wave-lengths  $\lambda = 540, 590 \text{ m}\mu$  as a function of intensity, ratio values can be calculated for the green bleaching lights. In a similar manner, theoretical values of  $\Delta D_{590}/\Delta D_{540}$  may be obtained for orange bleaching lights ( $\beta = 590 \text{ m}\mu$ ). The continuous curves of Fig. 5 show the results of these computations for the same areal distributions as before, and a maximum receptor density of the green-sensitive chlorolabe  $D_{1\lambda} = 0.15$ . As expected, the two curves converge at high values of  $I_{\beta}$  when both pigments are nearly exhausted by either spectral bleaching light. However, at lower intensities, when the bleaching is partial, varying the intensity of a green bleaching light barely affects the density ratios, that is, the shapes of the difference spectra are very nearly constant. For orange light, on the other hand, the density ratio and bleaching intensity exhibit an inverse relation, that is, the  $\lambda_{\max}$  of the difference spectra move towards shorter wave-lengths as  $I_{\beta}$  rises.

The data points in Fig. 5 were taken from the experimental results shown in Fig. 4. For a green bleaching light ( $\beta = 547 \text{ m}\mu$ ), experimental values agree with theory very well indeed. The 'red' data ( $\beta = 680 \text{ m}\mu$ ), however, show a ratio change greater than that predicted. But it should be noted that the computed values are for orange light, the data in Fig. 2 not being sufficiently accurate at the longer wave-lengths for use in the computations. It would be expected, therefore, that bleaching with deep

Fig. 3. Curves are the computed foveal density changes at two different measuring wave-lengths.  $D_{1\lambda}$  represents assumed maximum density values of the green-sensitive chlorolabe at the measuring wave-length  $\lambda = 540 \text{ m}\mu$ . For  $\lambda = 590 \text{ m}\mu$ ,  $D_{1\lambda} = 0.42 D_{1\lambda, 540}$  as estimated from Fig. 2. Experimental points give measured foveal density changes obtained from Fig. 4; open circles  $\lambda = 590 \text{ m}\mu$ , closed circles  $\lambda = 540 \text{ m}\mu$  (ref. 15)

Fig. 4. Human foveal difference spectra obtained by fundus reflectometry. Vertical axis gives density changes referred to double transit through retina. (a) Results with green bleaching light ( $\beta = 547 \text{ m}\mu$ ); (b) bleaching with deep red light ( $\beta = 680 \text{ m}\mu$ ). The Ilford 206 filter used transmitted 1 per cent or less of the incident radiation at wave-lengths  $< 630 \text{ m}\mu$  (ref. 15; by courtesy of the editors of *Vision Research*)

red lights yields greater density ratios at low intensities owing to more selective bleaching of the red-sensitive pigment by the longer wave-length light. As indicated earlier, a rise in intensity bleaches an increasing proportion of the green-sensitive pigment, resulting in the marked decrease of the density difference ratio.

**Individual receptors.** The remarkable achievements of Marks, Dobelle and MacNichol<sup>13</sup>, and of Brown and Wald<sup>14</sup>, who have measured the transmissivities of individual receptors in isolated human retinae, represent a significant advance in the study of visual pigments *in situ*. Although only a few cones have so far been sampled, and these from non-foveal regions, it would not be amiss to comment on some of these findings in the context of this paper.

One notes, for example, that the  $\lambda_{\text{max}}$  of the red- and green-sensitive pigments are not in agreement with those derived from *in vivo* measurements<sup>15</sup> and, in fact, used in the earlier computations. It is interesting, in this connexion, that Marks *et al.* and Brown and Wald suggest the possibility that, in some instances, both the red- and green-sensitive pigments may be housed in a single element. Furthermore, it is difficult to assess the effect on the pigments that may result from morbid changes which occur in excised retinae. Unknown also is the influence that photo-products may have on the shape of difference spectra measured in single receptors and in the living eye. However, important though such factors may be to a comparison of results obtained with different techniques, their significance for the computations presented previously is minimized because results obtained in the living eye were used to predict other results also obtained in the living eye. For the most part, whatever correction may be applicable to computed values will also be applicable to the experimental values on which they are based. As such coherence may not extend to results obtained under greatly different conditions, comparisons cannot be pressed with too much force to cover such conditions. However, if this proviso is borne in mind, an attempt can be made to reconcile measurements on single receptors and those on the living human fovea.

With regard to cone pigment densities, Marks *et al.* give the range of differential absorption for measurements obtained on the receptor and a retinal area free of visual cells, respectively. Their results, therefore, are not directly

comparable with data which provide the density differences produced by bleaching. However, Brown and Wald's measurements of difference spectra are amenable to a more detailed analysis. One notes, in the first place, that there is considerable variance between the density measurements on single human cones and those in the living eye<sup>9,13</sup>. Whereas application of equation (10) to the *in vivo* data suggests a chlorolabe density of approximately 0.15 (Fig. 3), Brown and Wald give a density of 0.025 for this pigment. For erythrolabe the difference is even greater, the single cell measurements being lower by a factor of almost 17 as compared with the computed value. But these discrepancies may result from a variety of circumstances including, as the authors suggest, the possibility that some bleaching had occurred before the receptor measurements had begun. In addition, Brown and Wald used one or two flash exposures for bleaching, and we have no reliable evidence as regards the efficacy of brief flashes in bleaching cone pigments. Hagins<sup>16</sup> has established that, no matter how intense, flash exposure of rabbit rhodopsin bleaches approximately only one-half the available pigment. There are also morphological differences between the regions examined in the two studies;

parafoveal cones are shorter than foveal, so that on this score alone one would expect Brown and Wald's  $\Delta D$  values to be less than those obtained for the fovea.

Perhaps a more important consideration concerns the fractional area of the measuring field occupied by pigment. It will be recalled that, in arriving at an *in situ* density of 0.15 for chlorolabe, we assumed that photolabile pigments contributing to the measured values of  $\Delta D_2$  occupy two-thirds of the total measuring area. This estimate was taken in view of the tight packing of the 'rod-like' foveal cones. But in para-foveal regions, the diameter of the cone inner segment is at least twice as large as that of the outer segment<sup>17</sup>. If Brown and Wald's technique led to the isolation of the former rather than the latter, application of equation (10) shows that the corrected receptor density (at  $\lambda_{\text{max}}$ ) would be more than four times greater than their measured values. Finally, since much of the preliminary procedures are performed under red light, the

Fig. 5. Ratio  $\frac{\text{density difference measured with } \lambda = 590 \text{ m}\mu}{\text{density difference measured with } \lambda = 540 \text{ m}\mu}$  as a function of bleaching light intensity and wave-length  $\beta$

extremely low density value for the red-sensitive pigment may have been caused by selective bleaching of this substance prior to measurement. The upshot of these considerations is that much of the apparent discrepancy as between measurements on the living human fovea and isolated cones may be resolved when more detailed information on the aforementioned factors becomes available.

## QUANTUM REQUIREMENT FOR ACETATE ASSIMILATION AND ITS SIGNIFICANCE FOR QUANTUM MEASUREMENTS IN PHOTOPHOSPHORYLATION

By DR. WOLFGANG WIESSNER

Institute of Molecular Biophysics and Department of Biological Sciences (Fels Fund), Florida State University, Tallahassee

TRUE photoassimilation of acetate under aerobic conditions is independent of the oxygen-evolving system of photosynthesis. This has been shown with the green member of the Volvocales, *Chlamydomonas*<sup>1,2</sup>, and with *Chlamydomonas mundana*<sup>3</sup>. Yet the dependence of the aerobic acetate assimilation on light implies an efficient mechanism to convert radiant energy into chemical energy, specifically into energy-rich phosphate, which is required for the transformation of acetate into cell material, carbohydrates<sup>1,4</sup>. A year ago we reported that *Chlamydomonas* assimilates acetate in near infra-red light<sup>5</sup>, which is known to be unsuitable for ordinary photosynthesis but not for photoreduction with hydrogen<sup>6</sup>. I have now determined the absolute quantum requirement for acetate photo-assimilation at different wave-lengths between  $\lambda$  450 and 740 m $\mu$ . Indirectly these measurements tell us something about the efficiency of photophosphorylation in an intact cell and its dependence on the light quality. The experimental arrangement was checked by measuring also the quantum yield of normal photosynthesis in *Scenedesmus obliquus*, where the light has to provide not only ATP\* but also the necessary NADPH<sub>2</sub>.

*Chlamydomonas stellata* Korschikoff was used in all experiments on acetate assimilation. The algae were cultivated in an acetate-containing medium in the light<sup>7,8</sup>. During the experiments the algae were kept in a closed cubic vessel inside a thermostat. The light sources were calibrated against the radiant energy of a standard carbon filament lamp (Eppley Laboratories, Inc., Newport, Rhode Island) measured with a large surface bolometer (H. Röhrig, Berlin, Germany)<sup>9</sup>. Interference filters (Schott and Gen., Mainz, Germany) were used to isolate narrow spectral regions. The light absorption of the algae was measured in an integrating sphere to minimize errors due to scattering<sup>10</sup>. The uptake of acetic acid by the algae was automatically recorded by titration with 0.01 N acetic acid at pH 7.0 ('Titrator TTT-1' with recording 'Titrigraph SBR2/SBU-1', Radiometer, Copenhagen). The quantum measurements on photosynthetic carbon dioxide fixation by the alga *Scenedesmus obliquus* D<sub>2</sub> were made using the same vessel at the same light intensities by retitrating the carbon dioxide consumed.

\*Abbreviations: NADPH<sub>2</sub>, reduced nicotinamide adenine dinucleotide phosphate; ATP, adenosine triphosphate; DCMU, 3-(3-dichlorophenyl)-1-dimethylurea.

Fig. 1. Quantum yields for photo-assimilation of acetate and photosynthetic carbon dioxide fixation at different wave-lengths. ●—●, Acetate assimilation, *Chlamydomonas*; x — x, photosynthesis, *Scenedesmus* D<sub>2</sub>.

Fig. 1 is the plot of the quantum yields for photo-assimilation of acetate and for photosynthetic carbon dioxide fixation at different wave-lengths derived from several series including hundreds of single measurements. The yield for acetate assimilation stays constant in the spectral region between  $\lambda$  450 and 680 m $\mu$  with an average of 0.083. It rises in the longer wave-length region beyond  $\lambda$  680 m $\mu$  to an average of 0.12. At  $\lambda$  740 m $\mu$  our measurements become unreliable because of the difficulties in measuring a very weak absorption. The quantum yields for carbon dioxide fixation and for acetate assimilation overlap in the spectral region below  $\lambda$  630 m $\mu$ . Beyond  $\lambda$  700 m $\mu$ , however, they fall apart.

Table 1 presents the quantum numbers for acetate assimilation from which the quantum yields have been calculated. Below  $\lambda$  630 m $\mu$  the assimilation of 1 mole of acetic acid requires on an average 12 mole quanta. Readings as low as 10.6 at  $\lambda$  671 m $\mu$  were repeatedly

Table 1. QUANTUM NUMBERS FOR PHOTO-ASSIMILATION OF ACETATE BY *Chlamydomonas* AT DIFFERENT WAVE-LENGTHS

Wave-length (mμ)	No. of expts.	Average Mole quanta/mole CH <sub>3</sub> COOH	Lowest quantum No. measured repeatedly
450	20	12.3 ± 0.75	11.3
547	24	11.8 ± 0.81	11.0
620	45	12.1 ± 0.41	10.5
650	16	12.1 ± 0.31	11.6
671	30	12.2 ± 0.71	10.6
680	21	11.8 ± 0.81	11.0
705	36	10.2 ± 0.39	8.8
716	18	8.3 ± 0.27	7.5
723	40	8.3 ± 0.26	6.8

obtained. Above  $\lambda$  680 mμ fewer quanta are required per mole acetic acid assimilated, on an average 8.3. Several times figures as low as 7.5 and 6.8 were registered at  $\lambda$  716 and 723 mμ.

Table 2 contains the quantum numbers for the photo-synthetic carbon dioxide fixation by *Scenedesmus*, a typical member of the Chlorococcales, which is often used in many laboratories. At  $\lambda$  620 and 680 mμ the lowest number measured was 9; in the near dark red at  $\lambda$  705 mμ, however, not smaller than 29. Because these numbers fit into the range of the most reliable quantum number determinations reported in the literature<sup>11,12</sup> they serve here as an independent check on our experimental set-up.

Table 2. QUANTUM NUMBERS FOR PHOTOSYNTHETIC CARBON DIOXIDE ASSIMILATION BY *Scenedesmus obliquus* D<sub>2</sub> AT DIFFERENT WAVE-LENGTHS

Wave-length (mμ)	No. of expts.	Average Mole quanta/mole CO <sub>2</sub>	Lowest quantum No. measured repeatedly
620	6	11.5 ± 0.74	9.0
671	24	12.0 ± 0.50	9.0
705	9	32.8 ± 1.62	29.0

Acetate assimilation does not change in the presence of  $5 \times 10^{-6}$  M DCMU, a poison concentration that is known to stop carbon dioxide fixation. This has been reported already for white light<sup>1,2</sup>, but, as can be seen in Table 3, it holds true also in monochromatic light.

Table 3. PHOTO-ASSIMILATION OF ACETATE IN THE PRESENCE OF  $5 \times 10^{-6}$  M DCMU AT DIFFERENT WAVE-LENGTHS

$\lambda$ mμ	Mole CH <sub>3</sub> COOH/mg chlorophyll/h (average of 7 expts.)
equal incident intensities	Control + DCMU
620	20 20
671	39 40
680	38 38
723	8 8

All the foregoing can be summed up by saying that in *Chlamydomonas* the quantum efficiency for fixing one molecule of acetate happens to be the same as that for photosynthesis so long as the light contains only wave-lengths shorter than  $\lambda$  680 mμ, but that above  $\lambda$  680 mμ, where photosynthesis is poor, the acetate assimilation becomes considerably more efficient.

Actually this statement applies not for the overall mechanism of acetate fixation, but only for the light requiring part of it, which so far as we know is the pro-

duction of energy-rich phosphate<sup>1</sup>. It follows that in this alga (and possibly also in others) the efficiency of photo-phosphorylation varies with the wave-length of the absorbed light. In present-day theoretical terminology we say it is high when the light is absorbed mainly by chlorophyll system I (beyond  $\lambda$  700 mμ)<sup>13,14</sup> and low when part of it is absorbed also by chlorophyll system II. The insensitivity against DCMU proves that system II cannot be involved and consequently also not the so-called 'photosynthetic phosphorylation' assumed to be coupled to the interplay between the light reactions of system I and those of system II (refs. 13, 14 and 15). If such a phosphorylation could contribute ATP in significant amounts for the fixation of acetate, the quantum yield of the latter should be constant throughout the entire spectrum. The apparently higher energy requirement at wave-lengths shorter than  $\lambda$  680 mμ must therefore be attributed to losses in absorbed light energy, which cannot be circumvented by a physical light energy transfer from the carbon dioxide reducing mechanism to that which induces acetate fixation<sup>16</sup>. This independence of two photochemical systems in *Chlamydomonas* (which shows a diminished ability for fixation of carbon dioxide) does not rule out the possibility that ATP formed in the near infra-red aids the fixation of carbon dioxide in the visible light when carbon dioxide is the only substrate available to the alga.

I thank Prof. H. Gaffron for his help and advice. This research was supported by a contract between the Office of Naval Research, Department of the Navy (NONR 988-(10)), and the Florida State University, and by U.S. National Science Foundation grant GB-345.

## AFLATOXINS AND 'ALBINISM' IN PLANTS

By DR. REGINA SCHOENTAL and A. F. WHITE

Toxicology Research Unit, Medical Research Council Laboratories, Carshalton, Surrey

SINCE the discovery of penicillin, a metabolite of *Penicillium notatum*, much effort has been devoted to the examination of fungal and microbial metabolites, with the view of finding new therapeutic drugs<sup>1</sup>.

A new aspect of the problem became apparent more recently, when metabolites of the fungus, *Aspergillus flavus*, Link ex Fries, known as aflatoxins, have been found in human and animal foods and been shown to possess exceedingly potent hepatotoxic and/or hepatocarcinogenic activity for several species of animals, including fish, birds and rodents<sup>2</sup>. These findings with their implications for human pathology exemplify the fact that metabolites of micro-organisms can have deleterious

effects not only on pathogenic microbes (which makes them useful as therapeutic agents) but also on cells of higher organisms, in which they can cause disease. It might be expected that some of these fungal metabolites might also affect plant cells, and interfere with the germination of seeds or plant growth, and cause wilting or blanching of leaves by interfering with some specific biochemical processes such as the biosynthesis of chlorophyll.

In 1938, Koehler and Woodworth<sup>3</sup> showed that 'virescence' (pallor of leaves) of corn seedlings, usually considered as a genetic characteristic, could be induced by inoculation with spores of *Aspergillus flavus* and *A. tamarii*. Similarly, Durbin<sup>4</sup> traced the 'albinism' of

Table 1. EFFECTS ON GERMINATION AND LEAF COLOUR OF SEEDLINGS OF CRESS, *Lepidium sativum* L.

G\*, percentage of explanted seeds which germinated. A†, albinism; ++ complete; + partial; ± doubtful.

seedlings of citrus plants to their contamination with *A. flavus*, and Perlberger and Reichert<sup>5</sup> found that 'albinism' could be eliminated when the seeds were disinfected with preparations containing heavy metals: mercury, copper, nickel and lead. On the other hand, Ryan *et al.*<sup>6</sup> induced 'albinism' in citrus and in certain other plants with the fungus *Alternaria tenuis*, or with its heat stable extracts, but could not reproduce such effects with the several species of *Aspergillus flavus*, which they tested.

Since the discovery of aflatoxins, various species of *Aspergillus flavus* have been subjected to intensive investigations, which revealed that only certain strains, under favourable conditions, produce the toxic metabolites, aflatoxins.

It was therefore of interest to find out whether aflatoxins may be the factors responsible for the inhibition of chlorophyll synthesis as observed in 'virescence' or 'albinism' of plants.

Crude extracts were prepared from two groundnut meals by a method (Method A) already described<sup>2</sup>. One meal was known to be toxic to animals and to contain aflatoxins, and the other was a non-toxic meal. These extracts were tested on the rapidly germinating seeds of cress *Lepidium sativum* L. The leaves of the seedlings that had the toxic extract (5 mg/ml. corresponding to approximately 0.5 g of meal) appeared yellowish, while those which had the same concentration of the non-toxic extract, or water, were bright green. Both extracts inhibited the germination of cress seeds at the concentration of 25 mg/ml., while only the toxic extract had some inhibitory effect on germination in concentration of 5 mg/ml. When crystalline preparations of aflatoxins became available the tests were repeated using various concentrations of aflatoxin(s). For comparison, similar tests were performed with other fungal metabolites, made available through the courtesy of Prof. J. H. Birkinshaw, and with certain other substances (for the structures of the various fungal metabolites see ref. 1). These included coumarin, a known inhibitor of germination, the action of which has recently been reviewed<sup>7</sup>.

For the test, twenty seeds of cress, *Lepidium sativum* L., were explanted on circles of surgical gauze placed in 2-in. Petri dishes containing 4 ml. of distilled water (controls) or of aqueous solutions, or suspensions, of the substances being tested. The Petri dishes were placed on a window sill, facing south-west, and left for seven days at room temperature. Germination usually became apparent on the third day. The appearance of the treated cultures was compared with that of the controls on the sixth or the seventh day; the conditions of the cultures deteriorated if kept longer. Alternariol and its methyl ether, asteric acid, 3,4-benzopyrene, citromyocetin, cycasin (a glucoside of methylazoxymethanol), cyclopolic acid, erdin, fuscine, kojic acid, luteoleosin, mineoluteic acid, quadrilineatin, retransins, sclerotiorin, spinulosin, sterigmatocystin, sulochrin, and dimethylnitrosamine had no detectable effect on the germination or colour of the seedlings when tested in concentrations up to 100  $\mu\text{g/ml.}$  under the conditions described.

Table 1 summarizes the effects of various concentrations of aflatoxin, coumarin and several other fungal meta-

bolites on the germination and on leaf-colour of cress seedlings.

Aflatoxin(s), like coumarin, inhibited the germination of seeds in concentration of 25  $\mu\text{g/ml.}$ , but its effect on the colour of leaves was more marked. Complete absence of the green colour occurred in the presence of 10  $\mu\text{g/ml.}$  of aflatoxin, and partial inhibition, with a characteristic bleaching of the edges of leaves, could still be recognized at 1  $\mu\text{g/ml.}$  Of the other compounds, some effect on germination and/or on colour could be discerned only with concentrations of 50–100  $\mu\text{g/ml.}$

It is of interest that compounds, representing several types of carcinogens, 3,4-benzopyrene, retrorsine, cycasin and dimethylnitrosamine, were completely inactive under the conditions tested.

The mechanism by which aflatoxins induce chlorophyll deficiency in plants can at present be only surmised; but this simple test could be used for the investigation of the biochemical processes involved, and of the factors which can modify them.

It would also be of interest to test whether strains of fungi, *Alternaria tenuis* and *Aspergillus tamaris*, which have been reported to induce 'albinism' in plants can also produce aflatoxins.

The striking effect of aflatoxin(s) in inhibiting the green colour of cress seedlings suggests that this effect could serve as the basis for a test for the presence of aflatoxins in foodstuffs suspected of being contaminated. The test requires neither special equipment nor technical skill, thus making it suitable as a field test under conditions where other methods are not feasible. The latter include: fluorescence<sup>2,8</sup> and ultra-violet absorption spectroscopy<sup>9</sup>, the 'duckling test'<sup>2</sup>, the 'egg test'<sup>10</sup> and tissue culture<sup>11,12</sup>. These methods require special apparatus and experience in handling and in interpreting the findings if misleading results are to be avoided.

The experiments recorded here demonstrated that aflatoxins can induce chlorophyll deficiency in cress seedlings and are possibly the cause of 'albinism' reported in certain other plants. This effect might be elaborated into a simple test for their detection in suspected materials.

We thank Prof. J. H. Birkinshaw for the crystalline specimens of the various fungal metabolites, and the Tropical Products Institute for the crystalline preparation of aflatoxins, containing mainly the B<sub>1</sub> aflatoxin.

## LETTERS TO THE EDITOR

## ASTROPHYSICS

## Growth of Interstellar Grains

It is now generally accepted that interstellar grains can grow by some form of accretion from the surrounding interstellar gas (and other grains) given suitable conditions, and this growth has been used in several astrophysical theories<sup>1</sup>. A number of authors, for example, McCrea and McNally<sup>2</sup>, and Hoyle and Wickramasinghe<sup>3</sup>, have devised methods by which such growth of grains can occur, although none has been universally accepted. In this communication we shall assume that a fixed proportion of the colliding particles adhere to the grain and, using a simple kinetic theory model, calculate the rate of growth of a grain moving at any speed through the cloud.

We shall assume that the cloud is so large that the amount of material accreted is small and does not alter the number density,  $n$ , of particles (which we shall regard as 'molecules' for kinetic theory purposes) forming the cloud. We also assume that the grain is small compared with the mean free path of the gas, which enables us to use an undisturbed (equilibrium) velocity distribution for the oncoming particles, which we take to be Maxwellian. In astrophysical situations of interest both these conditions are likely to be satisfied. We also make the usual assumption that the grains remain spherical throughout and that the grain density,  $\sigma$ , stays constant.

Let  $M$  and  $a$  be the mass and radius of the grain at any time  $t$ , and  $U$  the velocity of the grain relative to the gas cloud. Take a set of spherical polar co-ordinates ( $r, \theta, \phi$ ) with origin at the centre of the spherical grain and polar axis in the direction of  $U$ . An element of area at the surface of the sphere is  $dA = a^2 \sin \theta d\theta d\phi$ . At this element, but stationary with respect to the gas, take a second set of axes ( $x, y, z$ ) with the  $y$ -axis along the outward normal and the  $z$ -axis intersecting the line of action of  $U$ .

The probability of a molecule of the gas having speed between  $v$  and  $v + dv$  along the  $y$ -axis is  $(\beta/\pi)^{1/2} \exp(-\beta v^2) dv$ , where  $\beta = m/2kT$ ,  $m$  being the mass of a gas molecule and  $k$  and  $T$  being respectively Boltzmann's gas constant and the kinetic temperature of the gas. Thus the rate at which mass is added to the grain by molecules with speeds in this range colliding with the area  $dA$  is:

$$\lambda(\beta/\pi)^{1/2} mn(v + U \cos \theta) \exp(-\beta v^2) dv dA$$

$\lambda$  being the proportion of colliding gas molecules that adhere ( $U = |U|$ ).

The rate at which mass is added to the whole grain is found by integrating for all possible collisions over the surface of the sphere. Now if  $v \geq U$  collisions occur for all  $\theta$  between 0 and  $\pi$  (that is, over the whole sphere), while if  $|v| < U$  collisions occur only if  $\cos \theta \geq -v/U$  and if  $v \leq -U$  no collisions occur. Integrating and inserting these limits, the total rate at which mass is added to the sphere is:

$$\frac{dM}{dt} = a^2 \lambda mn (\beta/\pi)^{1/2} \left( \mathcal{I}_1 + \mathcal{I}_2 \right)$$

where  $\mathcal{I}_1 = \int_U^\infty dv \int_0^\pi d\theta \int_0^{2\pi} d\phi (v + U \cos \theta) e^{-\beta v^2} \sin \theta$

and  $\mathcal{I}_2 = \int_{-U}^U dv \int_{\cos^{-1}(-v/U)}^\pi d\theta \int_0^{2\pi} d\phi (v + U \cos \theta) e^{-\beta v^2} \sin \theta$

Integrating over  $\theta$  and  $\phi$ , we have:

$$\mathcal{I}_1 = 4\pi \int_U^\infty v e^{-\beta v^2} dv = (2\pi/\beta) e^{-\beta U^2}$$

$$\begin{aligned} \text{and } \mathcal{I}_2 &= 2\pi \int_{-U}^+ U \left( \frac{v^2}{2U} + v + \frac{U}{2} \right) e^{-\beta v^2} dv \\ &= 2\pi \left\{ \left( \frac{U}{2} + \frac{1}{4\beta U} \right) \operatorname{erf}(\sqrt{\beta} U) - \frac{1}{2\beta} e^{-\beta U^2} \right\} \end{aligned}$$

where  $\operatorname{erf}$  denotes the error function (see, for example, ref. 4). Thus we have:

$$\frac{dM}{dt} = 4\pi a^2 \sigma \frac{da}{dt} = 2\pi mn a^2 \lambda \left( \frac{\beta}{\pi} \right)^{1/2} \left\{ \frac{e^{-\beta U^2}}{2\beta} + \left( \frac{U}{2} + \frac{1}{4\beta U} \right) \left( \frac{\pi}{\beta} \right)^{1/2} \operatorname{erf}(\sqrt{\beta} U) \right\}$$

It is convenient at this point to define a molecular speed ratio  $S = \sqrt{\beta} U = (2/\sqrt{\pi}) U/W$ , where  $W$  is the thermal velocity of the gas. We obtain:

$$\frac{da}{dt} = \frac{mn\lambda W}{8\sigma} \left\{ e^{-S^2} + \left( S + \frac{1}{2S} \right) \sqrt{\pi} \operatorname{erf}(S) \right\} \quad (1)$$

an expression for the rate of increase of the radius of the grain at any speed  $U$ .

Consider now the following limiting cases.

(i)  $S < 1$  ( $U$  small, of order less than the thermal velocity). Expansion of the error function (see ref. 4) and the exponential function in equation (1) gives:

$$\frac{da}{dt} = \frac{\lambda mn W}{8\sigma} \left( 2 + \frac{2}{3} S^2 + O(S^4) \right)$$

Retaining the first term in the bracket only, we obtain  $\frac{da}{dt} = \frac{\lambda mn W}{4\sigma}$ , which can be integrated to give:

$$a - a_0 = \frac{\lambda mn W t}{4\sigma}$$

where  $a_0$  is the radius at some given time,  $t = 0$ . This is the expression found by Williams<sup>5</sup> for the case of  $U = 0$ . Moreover, inserting the numerical values  $W = 2 \times 10^5$  cm/sec,  $\sigma = 5$  g/c.c., and  $\lambda = 1$ , as used by Lindblad<sup>6</sup>, we obtain the formula:

$$M = 5.7 \times 10^{33} (\rho t)^3 \text{ g}$$

where  $\rho = mn$  is the density of the gas and  $t$  is measured in years, which corresponds well with Lindblad's expression  $M = 10^{34} (\rho t)^3$  g.

(ii)  $S > 1$  ( $U$  large, of order greater than the thermal velocity). In this case the expansion of the error function in (1) gives:

$$\frac{da}{dt} = \frac{\lambda mn W}{8\sigma} \left( 2S + \frac{1}{S} + O(e^{-S^2}) \right)$$

Again retaining the first term in the bracket only, we have:

$$\frac{da}{dt} = \frac{\lambda mn W S \sqrt{\pi}}{8\sigma} = \frac{\lambda mn U}{4\sigma}$$

or

$$\frac{da}{dx} = \frac{\lambda mn}{4\sigma}$$

Integration gives:

$$a - a_0 = \frac{\lambda mn}{4\sigma} x$$

where  $a_0$  is the radius of the grain at a given point  $x = 0$ . This was also found by Williams<sup>5</sup> using another method for the case of very large  $S$  (thermal velocity  $W$  negligible).

From the general expression (1) (and assuming  $U$  is constant) it appears that the grain size is proportional to

age, suggesting that grain size increases without limit. It must be noted that our model is only valid while the radius of the grain is appreciably less than the mean free path of the gas, and the result is only meaningful while this condition is satisfied. Moreover, in a more accurate theory  $\lambda$  would depend on the grain size at any instant, but in the absence of detailed knowledge of the mechanism by which the molecules adhere to the grains we have confined ourselves to a constant value of  $\lambda$ .

In this calculation we have assumed that all the material in the cloud belongs to one accretable gas; but it will not alter the calculation if the cloud is assumed to consist of a number of non-interacting gases of different types and their contributions to the accretion (with the appropriate individual gas parameters) are added. (In particular, one of the 'gases' can be the other grains forming part of the interstellar cloud.) Thus the growth of a grain moving through a cloud of material composed of different gases with different accretion parameters  $\lambda$  could be found.

We thank A. S. Asebiomo for checking the calculations in this communication.

### Neutrino Emission from Star-like Sources

In a previous communication<sup>1</sup> we reported some evaluations of the neutrino energy density in the universe taking into account the  $e^+ + e^- \rightarrow \nu + \bar{\nu}$  process in the pre-supernova stage of the stars. We found that this energy density may be higher than the energy density of the matter. Here we present a similar evaluation on the basis of the Mannino<sup>2</sup> hypothesis regarding the star-like objects. It is known that the optical power of these objects is about  $10^{46}$ – $10^{48}$  ergs/sec (ref. 3). According to Mannino<sup>2</sup>, this may be due to supernova explosions of as many as 4,000 a year. During the exploding stage the temperature of the stars goes up to  $10^9$ – $10^{10}$  K and the star begins to emit neutrino antineutrino pairs through annihilation of electron-positron pairs which at this high temperature are in equilibrium with the photons. The neutrino emission is of the same order and even higher of the photon emission<sup>4</sup>. Thus we can safely assume that the star-like sources emit  $10^{48}$  ergs/sec as neutrino power. Because the energies of these neutrinos are of the order of a MeV, we have an emission of  $\sim 10^{54}$   $\nu$ /sec/star-like source. (We can obtain these figures also supposing that each supernova inside the star-like object emits  $\sim 10^{45}$  ergs/sec as neutrino power; since we have  $10^{-4}$  supernovae/sec, and since the process goes on for about 200 days<sup>5</sup>, this is the same as saying that at each time we have  $10^{-4} \cdot 10^7 = 10^3$  supernova in the whole star-like, which means an emission of  $10^{45} \cdot 10^3 = 10^{48}$  ergs/sec from the star-like sources.)

Supposing that the star-like sources are young galaxies which are confined inside a shell out of the until now observed universe, we may have about  $10^8$  star-like (that is, one-tenth of the estimated number of galaxies<sup>6</sup>). Then we have  $10^{54} \cdot 10^8 = 10^{62}$   $\nu$ /sec. Since the process goes on for about  $10^8$  years (ref. 2), we have an output of  $10^{70}$  neutrino antineutrino pairs. On the whole universe, this makes a density of  $10^{70}/10^{84} = 10^{-14}$   $\nu$ /cm<sup>3</sup>. This figure is quite negligible with respect to the previous estimate<sup>1</sup> on the neutrino emission from the pre-supernova stage of the stars, and anyhow smaller than the energy density of the matter which is of the order of  $10^{-2}$  MeV/cm<sup>3</sup> (ref. 5).

If we suppose that our universe is pulsating we have an accumulation of neutrinos which are emitted in each phase of oscillation until an equilibrium is reached through the  $\nu + \bar{\nu} \rightarrow \gamma + \gamma$  process. But also in this case the density of neutrinos is smaller than that of the previous estimate<sup>1</sup>, although higher than the energy density of matter in the universe.

### GEOPHYSICS

#### Metamorphism and Mineral Identification by Gamma Ray Methods

It is usually from the investigations of mineralogy that an estimation of the grade of metamorphism is made, since the appearance of some minerals and disappearance of others—or the change of composition in a solid solution series—is often symptomatic of the intensity of metamorphism. "For example, biotite is a common mineral of metamorphic rocks; however, it does not occur in very low grade rocks, its composition then being represented by mixtures of muscovite and chlorite. Minerals of the epidote group are characteristic of low grade rocks. At higher grades of metamorphism these minerals are largely converted to anorthite which enters into plagioclase. In lowest grade rocks the plagioclase is nearly pure albite and it increases in calcium content as the grade of metamorphism increases"<sup>1</sup>.

The mineral plagioclase has the chemical formula  $(\text{Na,Ca})\text{Al}_2\text{Si}_2\text{O}_8$ . The expression  $(\text{Na,Ca})$  in the formula means that sodium and calcium are interchangeable in the atomic structure of the crystals. If sodium is preponderant the mineral is called albite, and if calcium is preponderant, anorthite.

In order to find accurately which element predominates in the mineral, one can perform a chemical, petrographic, or spectroscopic analysis. These analyses suffer from the fact that the specimen may not be representative of the rock and that the specimen has to be destroyed before it can be analysed. This is disadvantageous especially when one also wants to investigate the thermal conductivity (heat flow), elastic constants and atomic weights (wave propagation), and conductivity and susceptibility (electric and magnetic properties) of the same specimen. A non-destructive analytic method is therefore proposed here.

When specimens are available in the laboratory,  $\gamma$ -ray attenuation methods may offer a simple and non-destructive method of analysis. An absorber the bulk density of which is  $\rho$ , made up of a mixture of elements the mass attenuation coefficients of which are  $(\mu/\rho)_1, (\mu/\rho)_2, \dots$  will have an overall narrow beam mass attenuation coefficient for the primary photons which is given by  $\mu/\rho = \sum p_i(\mu/\rho)_i$  where  $p_i$  is the fraction by weight of the  $i$ th element, and  $\mu$  the linear absorption coefficient<sup>2</sup>.

The computed  $\gamma$ -ray absorption coefficients for the minerals plagioclase  $(\text{Na,Ca})\text{Al}_2\text{Si}_2\text{O}_8$ , chlorite  $(\text{Mg,Fe,Al})_4(\text{Al,Si})_2\text{O}_{10}(\text{OH})_2$ , and epidote  $\text{Ca}_2(\text{Al,Fe})\text{Si}_2\text{O}_{12}(\text{OH})$  for the energy range 0.01–100 MeV using Grodzstein's tables<sup>3</sup> are shown in Table 1.

In the energy range 0.1–5 MeV, Compton effect is the predominant interaction and only the electron density can be obtained. However, at very low energies where the photoelectric effect is predominant, and high energies

where pair production predominates, the interchangeable heavy and light elements in a mineral can be distinguished. This distinction does not seem to depend on the energy of the primary photons when once very low (< 0.1 MeV) or very high (> 5 MeV) energies are used. When the mineral is thus identified (for example, as anorthite or albite), the grade of metamorphism can be estimated and the specimen can be used to investigate its elastic, thermal, electrical and magnetic properties.

### World-wide Propagation of Impulsive Micropulsation Activity through the Ionosphere

THE actual configuration in space-time of micropulsation activity has long been the subject of controversy, and no single model has been able to explain all the features of the different types of micropulsations. This communication concerns the method by which impulsive *Pi* 2 (ref. 1) micropulsations spread over the Earth. Such micropulsations are recognized more easily on the night side of the Earth, although they can be detected on the daylight side also if not masked by other daylight micropulsations such as *Pc* 3, *Pc* 4 and *Pc* 5 (ref. 1).

The origin of *Pi* 2 micropulsations is still uncertain. Some investigators believe that they are oscillations of the field lines caused by a change in particle pressure when a large bunch of trapped energetic particles is dumped<sup>2</sup>. On the other hand, charged particles impinging in high latitudes have also been suspected as the origin<sup>3</sup>, and in this respect several possible mechanisms have been considered whereby a beam of charged particles streaming through the magnetospheric plasma could trigger instabilities in the hydromagnetic frequency range<sup>4-7</sup>. Whatever the mechanism of creation may be, a certain kind of eigenoscillation, perhaps Dungey's<sup>8</sup> torsional mode of hydromagnetic oscillations of a bundle of magnetic lines of force, seems to work as an intermediate process. Despite the rather irregular appearance of *Pi* 2 micropulsations, one can still detect the existence of characteristic periods in most cases. The bundle of lines of force intersects the ionosphere in two magnetically conjugate regions in mid to high latitudes, resulting in the generation of two electrojets and the spread of ionospheric currents to all points on the Earth<sup>9</sup>. Fig. 1 (ref. 10) shows the distribution of ionospheric currents at a certain instant in the case of a typical *Pi* 2.

The figure suggests that the polar electrojet (in the northern hemisphere in this case) exists in the auroral

region in the meridian plane around 2,300 L.M.T., and that the stream lines of ionospheric currents spread both east and west along latitude circles. Herron<sup>11</sup> has actually observed that *Pi* 2 disturbances start from the 2,300 L.M.T. meridian and propagate eastward as well as westward. He has also observed significant phase differences in corresponding micropulsation signals over distances of hundreds of kilometres, although independent investigations by other groups often show no phase difference for events observed at points separated in longitude by thousands of kilometres<sup>12</sup>. According to the theory of electromagnetic induction, a periodic magnetic disturbance in a conducting material propagates with phase velocity  $T^{-1/2}/\sqrt{\sigma}$ , where  $T$  is the period (sec) of the disturbance and  $\sigma$  is the specific conductivity (E.M.U.). If one takes  $\sigma = 5 \times 10^{-16}$  as the daily mean in the *E* region and  $T = 100$ , the phase velocity is about 40 km/sec, which agrees with the results obtained by Herron<sup>11</sup>. The phase velocity has also been observed to be smaller for longer period disturbances. It would be interesting to determine whether, in fact, the velocity is actually inversely proportional to the square root of the period.

The foregoing calculation is a crude order of magnitude estimate for the one-dimensional case assuming an isotropic medium. However, the results are consistent with the experimental evidence, and do seem to indicate a strong possibility that the above mode of propagation for *Pi* 2 micropulsations is correct.

Fig. 1. Equivalent overhead current system for a *Pi* 2 at 0036 U.T., December 26, 1957. The intensity of the electric current between two adjacent contours is  $5 \times 10^2$  amp (Jacobs and Sinno, 1960<sup>13</sup>). \*In the previous paper<sup>10</sup>, the phenomenon is referred to as *Pi*. *Pi* is the older nomenclature for *Pi* 2, and the minus sign means that it occurred in association with a negative bay in the auroral regions.

## PHYSICS

### Turbulent Flow Deposition of an Aerosol in Long, Thin Conduits

In relation to an air-sampling system installed in our high-activity handling building, we have carried out some investigations to determine the loss in mass of a solid-particulate cloud when passing, in a turbulent air flow, through different lengths of 10-mm inner diameter copper tubing.

The particulate cloud consisted of lithium hydroxide particles in the size-range  $0.05\mu$ – $1.5\mu$  with a mean size by mass of about  $0.5\mu$ .

The geometry of the tubing during a run was in the form of concentric rings (radius of curvature about 0.5 m) resting for the most part on a horizontal surface.

The tubing was thoroughly washed and dried after each run. We cannot offer any explanation for the peculiar results (Fig. 1). Moreover, a more or less thorough survey of available literature on micromeritics has

Fig. 1. Loss of  $\text{LiOH} \cdot \text{H}_2\text{O}$  particles in 10-mm diam. copper tubing during turbulent flow

Fig. 2. Deposition pattern of particles along the 10-mm diameter tube of 12.7 m length

yielded nothing that would suggest the existence of such a phenomenon.

We have also been able to ascertain the existence of the same phenomenon for tubes with inner diameter of 5 mm, 4 mm and 3 mm.

From our findings we may state the following:

(1) The length of conduit for which maximum deposition takes place,  $L_{\text{max}}$ , is independent of the velocity of the turbulent stream.

(2) If  $r$  is the inner radius of a given tube, then for all tubes:

$$\frac{r^2}{L_{\text{max}}} = 1.8 \times 10^{-4} \text{ cm}$$

(3) If  $L_{\text{min}}$  is the length of conduit for which minimum deposition takes place, then for all tubes:

$$\frac{r^2}{L_{\text{min}}} = 0.9 \times 10^{-4} \text{ cm}$$

In order to observe the physical pattern of the aerosol deposits on the walls of the conduit for which a maximum loss had been observed (Fig. 1), we atomized a solution of  $\text{Na}_2\text{CO}_3$  with a tracer of sodium-24 and passed it through a 12.7 m length of 10-mm diameter tube. Fig. 2 shows the pattern of deposition along the length of this tube.

The same experiment with a 22-m tube failed to reveal any pronounced patterns such as in Fig. 2.

We are proceeding at this stage to (a) measure the phenomenon in straight conduits; (b) plan experimental arrangements with which we can describe the values and behaviours of all the parameters involved, for example, pressure, velocity, particle sizes, etc.; (c) determine the effect on the phenomenon of using aerosols with different densities and also gases of various densities and viscosities.

We are interested in hearing from any investigators who have come across this phenomenon or who can offer any information along these lines.

## Nanosecond Heating of Aqueous Systems by Giant Laser Pulses

We have just been able to demonstrate heating of some pH-indicator systems within a few nanoseconds. We had suggested such very fast heating earlier<sup>1</sup>. At that time we were only able to demonstrate heating by a ruby-laser operating in its normal mode, associated with a flash of 600  $\mu$ sec duration.

To generate the heating pulse we used a ruby crystal in TRG laser, model 104 (Technical Research Group, Melville, New York). With the added rotating prism well aligned, we obtained an energy output of about one joule *Q*-switched, measured with TRG-power meter model 101. The shape of the output pulse was measured with a detection device containing an SD 100 photodiode of EG and G or a phototube RCA type 929 and connected to a travelling wave oscilloscope ('Tektronix 519') or to a fast-rise oscilloscope ('Tektronix 545' with *L*-plug-in unit). An illustration of the output pulse near threshold is shown on Fig. 1. Two pulses were generally obtained at full output (together 1 joule), about 100 ns wide and 200 ns apart, inherent to *Q*-switches operating with rotating prisms. Single pulses could have been obtained with a special attachment, which was not available to us, or by operation near threshold.

Fig. 1. Ruby laser pulse, *Q*-switched slightly above threshold, 50 mV per large vertical division, 100 ns per large horizontal division

The pulsed laser beam passed through a rectangular window and was slightly focused into a cell of 3 mm  $\times$  6 mm opening and 2 mm depth by two cylindrical lenses. The beam was directed so that no cell walls were touched. Perpendicular to the axis of the laser beam was the axis of the observation beam, such that it transversed a length of 6 mm. A well-aligned beam from a tungsten light source<sup>2</sup> was used. Its cross-sectional area within the small cell was about 1 mm. The monochromatic light (Schott double-band interference filter, peaking at 432 m $\mu$ ) was collected at the photocathode of a multiplier phototube (RCA type 7326). The voltage signal produced by the anode current of the multiplier phototube across the load resistor was d.c.-compensated and fed into 'Tektronix 535' with a *D*-plug in unit.

Fig. 2 shows an oscilloscope trace of an actual experiment. The aqueous solution in the cell contained 0.022 M CuSO<sub>4</sub>, 10<sup>-4</sup> M bromthymol blue, and 0.11 M triethanolamine, pH = 7.0 (23° C initially). A calibration experiment was conducted with available instrumentation<sup>3</sup>. It was found in the calibration experiment that a temperature change of about 3° C caused an equilibrium shift of about 20 mV (signal with mixture = 340 mV, with water alone = 4,500 mV, length of light path = 10 mm). Reduced to the 6-mm path length in the small cell for flash heating one should expect an equilibrium shift of the signal of 1.2 per cent/deg. C. The experiment resulted in a shift of 5 per cent (total signal with mixture = 60 mV, equilibrium shift = 3 mV). This corresponds to a temperature rise of 4° C.

The aqueous solution already mentioned had a transmission of 47 per cent, as measured with a Zeiss spectrophotometer at 694 m $\mu$  in a 2-mm cuvette. Then about 0.5 joule was absorbed in about 20 mm. One would

Fig. 2. Temperature jump experiment with a copper-complex absorbing the light pulse, 2 mV per large vertical division, 200 ms per large horizontal division. This large time scale was used to demonstrate the long duration of the change. These changes were measured thus far down to 10  $\mu$ sec/div.

therefore expect a temperature rise of 6° C. This value is somewhat above that derived before, but the deviation is acceptable on the grounds of the uncertainties involved in the measurements. The heating may also be less homogeneous than assumed, due to the structured pattern of the pulsed laser.

Fig. 3 shows an oscilloscope trace of another experiment, using 1.5  $\times$  10<sup>-4</sup> M methylene blue, 10<sup>-4</sup> M bromthymol blue, and 0.02 M glycylglycine (pH 7.3, 23° C). In a calibration experiment of 3° C temperature rise, an equilibrium shift of 6 mV occurred (240 mV signal, otherwise as before). A 6-mm path length in the small cell would result in a signal change of 0.4 per cent/deg. C. The experiment gave a change of 9.2 per cent, corresponding then to a temperature rise of 23° C. The spectrophotometric transmission at 694 m $\mu$  for a 2-mm path was 23.5 per cent, about 750 m joules are absorbed in 20 mm (ref. 3) solution, giving a 9° C temperature rise. As the experimentally derived temperature rise exceeds the theoretically possible one by a large amount, heating by the laser flash cannot account for the total change in transmission, measured at 432 m $\mu$ .

In an attempt to solve the lack of agreement, the absorbed laser energy was measured with a TRG-power meter, model 101. The absorbed energy was reproducible within 3 per cent (four flashes each) and corresponds to 30.5 per cent transmission for the methylene blue solution and 40 per cent for the copper-containing solution. While the transmission of the former solution increased by 7 per cent (photobleaching?), the transmission of the copper-containing sample decreased by 7 per cent. This decrease in transmission would follow directly from the heating effects. The temperature sensitive reaction is:

with *IH*, *I*<sup>-</sup> the two forms of bromthymol blue and

Fig. 3. Temperature jump experiment with methylene blue absorbing the light pulse, 2 mV per large vertical division, 200 ms per large horizontal division

$B$ ,  $BH^+$  those of the  $pH$ -buffer. The two wave-lengths indicate which form of the indicator absorbs there.

The experiments showing sudden rise in temperature demonstrated increased transmission at 432  $m\mu$  (Fig. 2), corresponding to production of  $I^-$ . The production of  $I^-$  is associated with a decrease in transmission at 694  $m\mu$ , as measured. Plotting extinction as a function of wave-length with  $pH$  as parameter shows that  $pH$  changes cause about equal extinction changes at both wave-lengths (but in opposite directions). The measured total shift of 5 per cent brings the observed transmission of laser pulses quite close to the expected value (42 per cent, neglecting absorption irregularities).

While nanosecond heating with the copper-containing solution seems fairly well established, such heating could only account for part of the effects of the methylene blue solution. Bleaching of the dye could account for most of the transmission increase at 432  $m\mu$  and at 694  $m\mu$ . This latter system is under further investigation.

### Electrical Conductivity of Circumanthracene

CIRCUMANTHRACENE is the largest of the polycyclic aromatics having known crystal structure. X-ray crystal structure analysis of the grey-black prismatic needles showed that they are monoclinic with  $a = 23.77 \pm 0.01$  Å,  $b = 4.59 \pm 0.03$  Å and  $c = 9.98 \pm 0.01$  Å and  $\beta = 99^\circ 54' \pm 30'$  (ref. 1). The evaporated thin film of this thirteen ring aromatic ( $C_{14}H_{10}$ ), obtained easily by means of a vacuum sublimation, was brownish violet.

The electrical conductivity and its temperature dependence have been found for three forms of the aromatic hydrocarbon; needle-type single crystal having dimensions:  $30 \sim 50 \mu \times 30 \sim 50 \mu \times 1$  mm, surface-type thin film and sandwich type film, both being about  $1 \mu$  in thickness<sup>2</sup>. To avoid the effect of humidity, the specimens used were kept in a vacuum of  $10^{-5} \sim 10^{-6}$  mm mercury. Depending on the orientation of the large molecules in the monoclinic crystal, a substantial anisotropy was found as listed in Table 1 (ref. 3).

Table 1. THE ELECTRICAL RESISTIVITY AT  $15^\circ$  C,  $\rho_{11}$ , OF CIRCUMANTHRACENE OBSERVED FROM THE VARIOUS TYPES OF CELLS: ( $\rho_{11} = \rho_0 \exp(\Delta E/2kT)$ )

Specimen	Observed value $\rho_{11}$ ( $\Omega$ cm)	$\Delta E$ (eV)
Single crystal// b-axis	$6 \times 10^{12}$	1.8
Surface-type	$2.5 \times 10^{13}$	1.9
Sandwich-type	$10^{14} \sim 10^{17}$	1.7

A fairly strong photoconduction of circumanthracene was observed. An excellent agreement of spectral responses between the optical absorption and the photoconduction in solid state was found as drawn in Fig. 1.

An abrupt change of electrical properties of films of pure circumanthracene was observed, when they were prepared under high vacuum ( $10^{-7} \sim 10^{-8}$  mm mercury), produced by an ion pump. When the preparation of surface-type cell, the evaporation of two aluminium electrodes and of the organic specimen, were carried out at high vacuum, the observed resistivity was  $10^3$  times higher than that of an ordinary cell.

However, when a small amount of dried oxygen was introduced to the high vacuum cell, a sharp drop of the resistivity was observed and the value converged to that observed under ordinary conditions.

This behaviour may be explained by a combination of the hydrocarbon molecules with ambient oxygen. The

Fig. 1. Spectral response curves of optical absorption (1) and photoconduction (2) for circumanthracene thin film

combination was so strong that removal of oxygen from the organic molecule was difficult at room temperature: an adsorption of oxygen on the circumanthracene molecules may be classified as a weak chemisorption.

Furthermore, the value of electrical conductivity of the sandwich-type cell, prepared under high vacuum, changed by a factor of  $10^6$  in comparison with that of a cell prepared under a vacuum of  $10^{-5} \sim 10^{-6}$  mm mercury. This drastic change may be explained by the fact that the introduction of electrons to the conduction band of circumanthracene from the aluminium metal increases the conductivity of the cell. The effect of ambient oxygen on the contact is to remove the electrons from the conduction band of circumanthracene and the conductivity decreases to the normal value.

### GEOLOGY

#### Marion Island, South Indian Ocean

MARION ISLAND lies in latitude  $46^\circ 49' - 46^\circ 59' S.$ , longitude  $37^\circ 35' - 37^\circ 55' E.$  It measures 12 miles east-west by 7 miles north-south, and rises to a maximum height of 3,890 ft. With the smaller Prince Edward Island, 12 miles to the N.N.E., it constitutes the Prince Edward Island group.

In contrast to many of the islands of the Southern Atlantic and South Indian Oceans, there is a lack of geological knowledge of these islands. Prince Edward Island has never been examined, and information on

Marion Island is restricted to the observations made during the short visits of the naturalists aboard H.M.S. *Challenger* in 1873<sup>1</sup> and of Jeannel<sup>2</sup> in 1938. By courtesy of the South African Navy, I spent several hours on the Island during the relief of the meteorological station there in April 1954. At that time, a thorough geological examination of the Island appeared imminent. As this has yet to materialize, the following note on the geology is submitted.

The Island is wholly volcanic. A younger and an older lava series are present, with intercalated agglomerate, and numerous large scoria mounds. Most of the Island is built up of the older lavas, chiefly dark-coloured olivine-basalts varying in their degree of compaction, and often carrying phenocrysts of olivine. There are also several light-coloured flows with a distinctive platy habit, for example on Skua ridge, 1½ miles north-west of the meteorological station. An agglomerate, with rounded fragments of olivine basalt up to 6 in. in diameter, was also noted interbedded with the normal olivine basalt.

Microscopic examinations of the normal basalt showed it to contain phenocrysts of magnesian olivine, and also of plagioclase and clinopyroxene, set in a dark matrix comparatively rich in iron ore. The platy lavas have a relatively even grain and contain less basic plagioclase. They are trachytes.

Several of the established valley floors have been inundated by flows of later olivine basalt. The most distinctive feature of Marion Island from offshore is the very numerous reddish scoria mounds dotted all over the Island. These rise for up to 700 ft. above their surroundings. Their conical shape is frequently perfectly preserved, and some retain crater-shaped depressions at their summits.

The age of the older lavas is uncertain. Behind the cliffed coastline the lower slopes of the Island locally exhibit a mature land surface. By analogy with other oceanic islands, they may date back as far as the Tertiary. The later lavas and scoria mounds are clearly of very recent age.

## METALLURGY

### Effect of Oxygen Pressure on the Melting of Silver

OWING to the high solubility of oxygen in the liquid metal, the melting or freezing point of silver decreases considerably with increasing pressure of oxygen<sup>1</sup>.

For the present investigations in oxygen under pressure a high-pressure furnace was used. This consisted of a resistance element of platinum 10 per cent rhodium alloy, 1.2 cm in diameter and about 24 cm long, enclosed in a pressure vessel 5.5 cm in diameter. Furnaces of this type and ancillary equipment have already been described<sup>2</sup>.

For some of the measurements up to 20 atmospheres, 7 g of silver were heated in a silica crucible in oxygen to a temperature about 25° above the expected melting point, kept constant for 40 min, then cooled at the rate of 2° per min. The solidification was shown by an arrest in the plot of the E.M.F. from a silica-sheathed thermocouple immersed in the sample. Results agree fairly well with those of Allen<sup>3</sup>, who used a similar method up to 13.9 atmospheres. At higher pressures, possibly due in part

Fig. 1. Melting point of silver as a function of oxygen pressure. x, Allen: thermal arrest; Δ, present work: thermal arrest; O, present work: fusion of silver strip

to greater heat losses, the arrests were indistinct and an alternative method was used: a silver strip about 6 mm long, 1 mm wide and 0.09 mm thick was roughened with emery paper and the ends welded to two stout gold wires. A thermocouple (Pt-Pt + 13 per cent Rh) was placed alongside the strip. Through the strip a small direct current of about 5 m.amp was passed; this was recorded on a meter. With a heating rate of 1.5° per min, fusion of the silver was shown by a zero reading on the meter. A modification was tried in which the ends of the strip were welded to wires of platinum and platinum-13 per cent rhodium respectively and incorporated in a differential thermocouple unit by means of the thermocouple alongside it. Fusion was shown as a break in the trace of the differential E.M.F. Owing to oxidation of the welds at pressures above 60 atms., this method was less reliable than the former, which was principally used. Agreement between the last methods, however, was good.

At a pressure of oxygen of 1 atm. the melting point is 937° C. For pressures and temperatures in the range 0.213-2 atms. and 950°-928° C respectively the solution of oxygen in the liquid metal is dilute and the silver should behave practically ideally. From the freezing point depressions, taking the heat of fusion of silver<sup>4</sup> as 2,855 cal. mole<sup>-1</sup>, the atom fractions of silver ( $X_{Ag}$ ) have been determined. If the other atom fractions are assumed to be atomic oxygen, the relation  $X_0 = k\sqrt{P_{O_2}}$  is found to apply. The solubility of oxygen in the solid silver is too small to affect the relationship significantly. The mean value of  $k$  for the range is approximately 0.022. The same value is obtained by extrapolation of the higher-temperature data of Sieverts and Hagenacker<sup>5</sup> to this region.

Results for the pressure range 0.213–147.3 atm. are shown in Fig. 1. At the highest pressure, after allowance for a slight scatter, the melting point is approximately 736° C, showing a depression of 225°.

## CRYSTALLOGRAPHY

### Layer Diameter in Graphite

THE X-ray method of estimating the layer diameter in samples of graphite, based on the breadths of the  $hk0$  reflexions, leads to apparent diameters of a few hundred Å. On the other hand, electron micrographs of the same sample show flakes the dimensions of which are some thousands of Å, nearly an order of magnitude larger. The discrepancy could arise from the simultaneous occurrence of strain broadening and particle-size broadening, or from the 'tangent-plane approximation'<sup>1,2</sup> being insufficiently good. The only  $hk0$  reflexion which can readily be examined is 1120, and measurements of integral breadths or half-widths require two reflexions in order to separate strain broadening and particle-size broadening. Measurement of the variance of a line profile, on the other hand, can in principle separate the two effects even when only one line is available for examination<sup>3</sup>. Use of the variance also makes it possible to allow for some departure from the conditions within which the tangent-plane approximation is valid.

The tangent-plane approximation leads to good results so long as the regions of high intensity in reciprocal space are concentrated near the points of the reciprocal lattice or, if not concentrated, at least have their directions of greatest extension making an angle other than 90° with the vector joining the reciprocal-lattice point to the origin. This limitation is well recognized when the disorder in layer stacking is complete<sup>4</sup>, but it has not always been taken into account for degrees of disorder of the kind encountered in samples of commercial graphite. In these the probability of a mistake in a layer sequence is of the order of one-fifth, and hence the  $hk0$  reflexions have a considerable extension in the direction of  $c^*$ , though they do not form continuous rods in reciprocal space. The tangent-paraboloid approximation<sup>4-6</sup> is appropriate for this problem. If  $S = 2 \sin \theta / \lambda$  is the distance from the origin of reciprocal space to any point in reciprocal space, and  $S_0$  is the distance to the  $hk0$  point, one can define a variable  $s$  by  $S = S_0 + s$ , so that:

$$S^2 = (S_0 + s)^2 = S_0^2 + 2S_0s + s^2 \quad (1)$$

If  $u, v, w$ , are the co-ordinates of a point in reciprocal space measured from  $S_0$ , then, with  $u$  parallel to  $S_0$ :

$$S^2 = (S_0 + u)^2 + v^2 + w^2 \\ = S_0^2 + 2S_0u + u^2 + v^2 + w^2 \quad (2)$$

These two equations for  $S^2$  must be equal, and a consideration of the relative magnitudes of the various terms shows that if  $w$  is measured in the direction of  $c^*$  the terms in  $u^2, v^2$ , and  $s^2$  are negligible in comparison with the rest. To a sufficient approximation, therefore:

$$s = u + w^2/2S_0 \quad (3)$$

The variance of  $s$  (Wilson<sup>7</sup>) is given by:

$$W_s \equiv \langle s^2 \rangle - \langle s \rangle^2 = \langle u^2 \rangle + \langle uw^2 \rangle / S_0 + \langle w^4 \rangle / 4S_0^2 - \langle u \rangle^2 - \langle u \rangle \langle w^2 \rangle / S_0 - \langle w^2 \rangle^2 / 4S_0^2 \quad (4)$$

The terms containing  $\langle u \rangle$  are practically zero, because  $u$  takes on positive and negative values with approximately equal probability. The remaining terms are the variance of  $u$  and the variance of  $w^2$  divided by  $4S_0^2$ :

$$W_s = W_u + W_w / 4S_0^2 \quad (5)$$

The tangent-plane approximation gives only the first of these terms. It is clear that if the observed variance  $W_s$  is attributed entirely to restricted particle dimension in the direction of  $u$ , the value obtained for the particle dimension will be too small, because: (1)  $W_u$  will result both from strain variance and particle-size variance; (2) the observed variance  $W_s$  depends also on the variance of  $w^2$ . The value of the variance of  $w^2$  required to correct the observed variance to give  $W_u$  only could be obtained, in principle, from the line profiles of the  $hkl$  reflexions, or from the theoretical expression for the line profile as a function of  $w$ . A tangent-paraboloid calculation for the integral breadth of the  $hk0$  reflexions would probably lead to a contribution from extension in the direction of  $w$  also, though Bacon<sup>6</sup> found that the half-width was relatively insensitive to variations in the perfection of the layer stacking.

We have made a preliminary examination of three samples of commercial graphite, for which the integral breadths of the 1122 reflexions indicate that mistakes in the layer sequence occur about every six planes, and the use of the ordinary Scherrer formula for particle size indicates layer diameters of 200 Å–500 Å. The line profiles of the 1120 reflexions were recorded with a counter diffractometer, and the variances calculated in a manner similar to that of Langford and Wilson<sup>8</sup>. A diamond-powder specimen, with approximately the same packing density as the graphite specimens, was used to correct for instrumental and wave-length broadening, and an approximate value for  $W_w$  was based on the integral breadths of the 1122 reflexions. The layer diameters obtained are subject to large error, since they depend on small differences between larger quantities, one of them being difficult to assess accurately at the present stage. Two of the samples showed no signs of heterogeneity, and gave apparent layer diameters of 3000 Å–4000 Å. The third graphite appeared to be composite, with the reflexions showing sharp and diffuse components simultaneously. The apparent layer diameter was 160 Å, in fair agreement with earlier X-ray measurements, and is presumably typical only of the component producing the diffuse lines. The intercepts of the variance-range curves indicated that some part of the breadth of the 1120 reflexions was caused by strain in the layers. However, the accuracy achieved was not high, and at the present stage of the analysis we do not feel justified in giving a numerical value for the strain.

## CHEMISTRY

### Safety in Air Separation Plants : Determination of Atmospheric Pollutants by Gas Chromatography

MANY problems are associated with safety in air separation plants, and various theories have been proposed as to the cause, and avoidance, of explosions<sup>1-3</sup>. The primary cause is known to be the accumulation of atmospheric pollutants, condensed from the air stream at the very low temperatures involved in liquid air distillation, particularly in the presence of high oxygen concentration. The nitrogen plants designed by this company minimize possible hazard by limiting the maximum oxygen concentration to 31 per cent.

The levels and type of contaminant will obviously vary considerably from site to site, depending on the extent of industrialization and traffic concentration. Consequently, an investigation of safety in air separation must be preceded by a detailed analysis of atmospheric pollutants, and this initial part of the research programme consisted of analysing hydrocarbons up to *n*-pentane.

Bellar *et al.*<sup>4</sup> demonstrated that flame ionization detectors are capable of analysing atmospheric hydrocarbon pollutants to levels of 0.001 volumes per million (v.p.m.) without resorting to concentration techniques. An analyser constructed at these laboratories, incorporating a Perkin Elmer model 451 ionization amplifier and flame ionization detector, was used in our work. In contrast to Bellar, 5 ml. samples were analysed, and we would confirm that, even with this sample size, the suggested flows of 40 ml./min hydrogen, 140 ml./min oxygen and 40 ml./min carrier gas allow re-ignition of the flame without difficulty and the base line re-establishes itself before elution of the first component.

Past experience gained from the analysis of gases and liquids derived from thermal naphtha cracking had resulted in the development of a two-column separation from air, hydrogen, etc., to *n*-pentane. The separation of methane to propylene was satisfactorily attained on a 6-ft. × 0.25-in. outer diam. column of 3 per cent di-2-ethyl-

Fig. 2. 1, Methane; 2, ethane-ethylene; 3, propane-acetylene; 4, propylene; 5, iso-butane; 6, *n*-butane; 7, *n*-butene-1; 8, iso-butene-1; 9, *trans*-butene-2; 10, *cis*-butene-2; 11, 1:3-butadiene; 12, iso-pentane; 13, *n*-pentane

hexyl sebacate on 30-60 mesh Davison silica gel (column 1), while for the *C*<sub>4</sub>'s separation a 14-ft. × 0.25-in. outer diam. column of a 2:1:1 blend of the coated supports 20 per cent *bis* (2-methoxyethyl) adipate and a 20 per cent di-2-ethylhexyl sebacate on 'Chromosorb P' (ref. 5) (column 2) was used. The retention values for this column, previously unpublished, are given in Table 1, but it should be noted that a modified column is now available from Perkin Elmer<sup>6</sup>.

Table 1. RELATIVE RETENTION TIMES (*n* C<sub>4</sub> = 1.000)

Component	R.R. time	Component	R.R. time
Air-methane	0.155	iso-Butene-1	0.512
Ethane-ethylene	0.183	<i>trans</i> -Butene-2	0.813
Acetylene-propane	0.252	<i>cis</i> -Butene-2	0.691
Propylene	0.280	1:3-Butadiene	0.733
iso-Butane	0.358	iso-Pentane	0.805
<i>n</i> -Butane	0.401	<i>n</i> -Pentane	1.000
<i>n</i> -Butene-1	0.450		

As expected, high acetylene-levels were recorded, but wide fluctuations were found throughout the day, while the *C*<sub>4</sub>'s were surprisingly high and relatively consistent, and were often individually greater in quantity than the more commonly expected impurities. Fig. 1 is a chromatogram obtained at a period of high acetylene concentration, using column 1 at 50° C and a helium flow of 40 ml./min, while Fig. 2, using column 2 at 50° C and 40 ml./min helium, shows high *C*<sub>4</sub> concentrations. A comparison of the chromatograms indicates the very wide fluctuations found during analysis, since the samples were taken within 4 h of each other. Table 2 gives the actual concentration of each component.

Table 2

Peak No.	Component	Concentration (v.p.m.)	Peak No.	Component	Concentration (v.p.m.)
1	Methane	0.001	1	Methane	0.01
2	Ethane	0.001	2	Ethane-ethylene	0.003
3	Ethylene	0.004	3	Propane-acetylene	0.028
4	Propane	0.001	4	Propylene	0.036
5	Acetylene	0.220	5	iso-Butane	0.102
6	Propylene	0.008	6	<i>n</i> -Butane	0.002
7	<i>C</i> <sub>4</sub> 's	0.012	7	<i>n</i> -Butene-1	0.09
			8	iso-Butene-1	0.12
			9	<i>trans</i> -Butene-2	0.114
			10	<i>cis</i> -Butene-2	0.053
			11	1:3-Butadiene	0.018
			12	iso-Pentane	0.006
			13	<i>n</i> -Pentane	0.007

A comparison of these results with the now classical work of Altschuller and Bellar<sup>6</sup> shows major differences. The methane quantities recorded are very much smaller and the number and quantity of *C*<sub>4</sub>'s considerably higher.

The samples for all the results given in this communication were taken from the centre of Trafford Park, Manchester, which is one of the world's largest industrial

Fig. 1. 1, Methane; 2, ethane; 3, ethylene; 4, propane; 5, acetylene; 6, propylene; 7, *C*<sub>4</sub>'s

estates, and several large chemical manufacturing companies are situated very close to these laboratories. While the atmospheric pollutants found in this area are very different from samples taken in other less industrialized areas, the installation of air separation plants is more likely to occur in the industrialized areas, and thus the results obtained are of more interest to the plant designer than those from other cleaner districts.

### Isolation and Preliminary Characterization of Soil Polysaccharides

SOIL polysaccharides, important components of humus<sup>1</sup>, are of microbial origin<sup>2</sup>. Their role in the formation of soil aggregates is of considerable significance in agriculture. We have, during the initial stages of our examination of the mechanistic role of polysaccharides in soil, concentrated on the isolation, purification, and the preliminary characterization of some components of the soil polysaccharide mixture.

Aliquots (200 ml. of liquid in all cases) of water, a 25 per cent aqueous suspension of 'Amberlite IRC-50(H)', 7 per cent disodium ethylenediamine tetraacetate, dimethylformamide, *N*-methyl-2-pyrrolidone, 8 M urea, and 0.6 N sulphuric acid were used to extract 100 g samples of the partially humified surface horizon of a Fenland soil (in cultivation for 20 years) with a pH of 6.0 and containing 80 per cent organic matter. The extract yields, calculated as organic matter, were 7.5 mg, 132 mg, 440 mg, 24 mg, 32 mg, 456 mg and 31 mg, respectively, for the different systems. A yield of 3 g was obtained when 100 g of soil was hydrogen ion saturated prior to extraction with dimethylformamide. The organic matter in the sulphuric acid extract contained 29 per cent polysaccharide which could be separated from coloured ( $\lambda_{\max}$  325 m $\mu$ ) components of the mixture by gel filtration through 'Sephadex G-100' (ref. 3). All other organic materials extracted contained less than 11 per cent polysaccharide. It was not possible to separate the polysaccharides in these from the coloured components on 'Sephadex'. After treatment of the organic matter extracted by urea with 0.1 N hydrochloric acid for 48 h at 0°, it was possible to separate 17 per cent of the material, mainly polysaccharide, from the dark coloured components on 'Sephadex G-100'. It was concluded that dilute acid was necessary to liberate polysaccharide materials in appreciable amounts from the coloured constituents of soil organic matter. Dilute sulphuric acid was used in subsequent extractions.

The soil (5 kg, containing 60 per cent water) was extracted for 24 h at 3° with 0.6 N sulphuric acid (10 l.). The filtrate was neutralized with sodium bicarbonate to give a solution *A* and a precipitate *B*. Solution *A* was exhaustively dialysed against water, then freeze-dried to give a crude polysaccharide mixture, *A* (4 g). Precipitate *B*, dissolved in 0.3 N hydrochloric acid, was dialysed successively against 0.3 N hydrochloric acid and water, then freeze-dried to give a crude polysaccharide mixture *B* (3 g). Only the first sulphuric acid extract was used in our experiments, though it was shown that appreciable amounts of polysaccharides were present in the sixth acid extract from the same soil sample. Separate frac-

Fig. 1. Separation, by stepwise elution (*A''* fractions) and by gradient elution (*B''* fractions) with sodium chloride solutions, of soil polysaccharides on DEAE 'Sephadex A-50'

tions of aqueous solutions of *A* and *B* on 'Sephadex G-100' (5.5 cm × 100 cm) resolved colourless polysaccharide materials (*A'* 1 g and *B'* 0.6 g) in the 400–1,400 ml. eluate from the column from the coloured ( $\lambda_{\max}$  325 m $\mu$ ) lower molecular weight fractions (*A'* 2.6 g and *B'* 1.5 g) in the 1,400–2,300 ml. eluate. The investigations reported hereafter deal only with the high molecular weight polysaccharides *A''* (200 mg) and *B''* (150 mg) appearing in the 400–650 ml. eluates.

Free-boundary electrophoresis of saturated (0.7 per cent) solutions of *A''* in phosphate buffer (pH 7.0;  $\mu$  = 0.1) indicated the presence of one essentially neutral and of five negatively charged components. The relative descending mobilities were  $-0.14$ ,  $-0.52$ ,  $-1.05$ ,  $-1.46$ , and  $-2.11 \times 10^{-5}$  cm<sup>2</sup> volt<sup>-1</sup> sec<sup>-1</sup> at 0°. Stepwise elution (Fig. 1) of 75 ml. of 0.4 per cent *A''* solution from a 4 cm × 80 cm DEAE 'Sephadex A50' (Cl<sup>-</sup> form) column in phosphate buffer (pH 6.0;  $\mu$  = 0.05) with the buffer (350 ml.), 0.3 M sodium chloride (400 ml.), 0.6 M (500 ml.) and 1.0 M sodium chloride (550 ml.) gave, after dialysis and freeze-drying, polysaccharides *A''*<sub>1</sub> (80 mg), *A''*<sub>2</sub> (60 mg), *A''*<sub>3</sub> (120 mg) and *A''*<sub>4</sub> (40 mg). A previous experiment with a 0.2–2.0 M sodium chloride linear gradient had indicated that negatively charged polysaccharides could be removed with the sodium chloride concentrations selected. Electrophoretic examination of a saturated solution of *B''* (0.03 per cent at 4°) showed the presence of one major negatively charged component with a mean relative descending mobility of  $-1.45 \times 10^{-5}$  cm<sup>2</sup> V<sup>-1</sup> sec<sup>-1</sup> at 0° and also trace amounts of a fast moving component in the phosphate (pH 7.0;  $\mu$  = 0.1) buffer used. However (Fig. 1), elution at room temperature of 60 ml. of a 0.17 per cent solution of *B''* in phosphate buffer (pH 7.0;  $\mu$  = 0.05) with a linear gradient (0.1 M) of sodium chloride (1,800 ml. for a 3.4 × 65 cm column) gave, after dialysis and freeze-drying, fractions *B''*<sub>1</sub> (23 mg), *B''*<sub>2</sub> (6 mg), *B''*<sub>3</sub> (29 mg), and *B''*<sub>4</sub> (37 mg).

By means of paper chromatography glucose, galactose, mannose, xylose, arabinose, rhamnose, fucose and glucuronic acid were detected in the hydrolysates (1 N sulphuric acid for 6 h at 100°) of *A''* and *B''*. The molar ratios (rhamnose = 1) of sugars in fractions *A''*<sub>1</sub>, *A''*<sub>2</sub>, *A''*<sub>3</sub> and *A''*<sub>4</sub>, determined by microcolorimetric methods, are presented in Table 1.

Amino<sup>3</sup> and keto<sup>4</sup> sugars were not detected. The equivalent weights of the fractions, as determined by titration with 0.02 N sodium hydroxide of the polysaccharide fractions passed through 'Amberlite IRC-50

Table 1. RATIO OF SUGARS (RHAMNOSE=1) IN POLYSACCHARIDES  $A'_1$ ,  $A'_2$ ,  $A'_3$ , AND  $A'_4$ , FRACTIONATED ON DEAE 'SEPHADEX 4-50'

Sugar	Ratio in			
	$A'_1$	$A'_2$	$A'_3$	$A'_4$
Pentose <sup>a</sup> (expressed as xylose)	0.27	0.6	0.96	0.76
Glucose <sup>a</sup>	2.6	0.9	—	0.23
Galactose <sup>a</sup>	1.25	—	1.87	0.07
Mannose <sup>a</sup>	4.5	3.6	3.24	2.96
6-Deoxyhexose <sup>a</sup> (expressed as rhamnose)	1.0	1.0	1.0	1.0
Glucuronic <sup>a</sup>	0.11	0.32	1.67	1.13

(H)' resin, were 17,100, 1,860, 1,220 and 600 for  $A'_1$ ,  $A'_2$ ,  $A'_3$  and  $A'_4$ , respectively. Comparison of the uronic acid content and equivalent weight data for  $A'_4$  indicates that uronic acid was only a minor constituent of the total acid in this fraction.

### Factors influencing the Formation of Some Polysaccharide-halogen Complexes

THE 'amyloid reaction' frequently used in the staining and identification of plant materials<sup>1</sup> has been modified by Gaillard<sup>2</sup> as a test to distinguish between linear and branched polysaccharides. Linear polysaccharides are precipitated from 1 per cent solution in 30 per cent aqueous calcium chloride by the addition of aqueous potassium iodide-iodine solutions, whereas branched polysaccharides are not. An examination of this reaction has been carried out to investigate its possible use in wood chemistry.

Various linear polysaccharides such as  $\alpha$ -cellulose, salep mannan, amylose, glucomannan from red alder<sup>3</sup> and ivory nut mannan gave dark blue or blue-black precipitates under the conditions of the test in agreement with Gaillard's results<sup>2</sup>. Pectinic and pectic acids did not form precipitates when iodine was added.

Extensive branching in polysaccharides prevented the formation of iodine complexes in agreement with Gaillard's results<sup>2</sup>. Examples of polysaccharides with filiform branches behaving in this manner include amylopectin, arabinogalactan from western larch, cherry gum and gum arabic. Polysaccharides with many short terminal branches such as guar gum and locust bean gum behaved in a similar manner. Galactoglucomannans from coniferous woods possessing terminal galactose branches similar to those of guar and containing galactose, glucose and mannose in molar ratios of 1 : 1 : 3 (refs. 4 and 5) to 0.5 : 1 : 3 (ref. 5), did not form precipitates, but coniferous galactoglucomannans containing molar ratios of 0.3 : 1 : 3 to 0.1 : 1 : 3 to 0.03 : 1 : 3 (refs. 4 and 6) formed heavy blue-brown precipitates, the browning cast of which was proportional to the amount of terminal galactose branches. Mixed solutions of galactoglucomannan (0.04 : 1 : 3) and guar gum in 30 per cent calcium chloride solution

having an average ratio of galactose, glucose, and mannose of 1 : 1 : 3 gave dark blue precipitates with iodine which were characteristic of the slightly branched component. Other polysaccharides with short terminal branches such as 4-O-methylglucuronoxylans from deciduous woods gave blue-black precipitates under the test conditions. Although softwood 4-O-methylglucuronarabinoxylans gave a doubtful test under these conditions, a 4-O-methylglucoarabinoxylan gave a dark blue precipitate with iodine.

A cellodextrin of low but undetermined molecular weight formed a precipitate under the test conditions, but none of the glucose-containing oligosaccharides from cellobiose up to cellohexaose gave precipitates. Decreasing the molecular weight of linear ivory nut mannan resulted in less complete complex formation. Xylobiose and xylotriose gave light brown, xylotetraose darker brown, and a xylodextrin mixture gave dark purple precipitates when iodine was added to their solutions in 30 per cent calcium chloride.

An examination of the effects of other multivalent salt solvents on the formation of iodine complexes showed that coniferous glucomannan (0.1 : 1 : 3) could not be precipitated from aqueous solutions of iron, copper, nickel or cobalt chlorides. This polymer could be precipitated from solutions in saturated or 30 per cent aqueous aluminium chloride, magnesium chloride, and barium chloride.

Precipitates of an iodine complex could be obtained when 45 per cent zinc chloride was used as a solvent for  $\alpha$ -cellulose, amylose, and ivory nut mannan. Hardwood glucomannans and salep mannan were not precipitated from this solvent when solutions of iodine were added, in contrast to the result in 30 per cent calcium chloride. Quantitative tests using 45 per cent zinc chloride as a solvent showed that glucans and galactose-deficient glucomannans were preferentially precipitated from crude coniferous galactoglucomannan preparations<sup>6</sup> when iodine was added.

The addition of bromine to a solution of elm 4-O-methylglucuronoxylan in 30 per cent calcium chloride resulted in the formation of a bright orange precipitate. Black spruce galactoglucomannan (0.1 : 1 : 3) gave a less well-defined test with bromine, while coniferous galactoglucomannan (1 : 1 : 3), gum arabic, 4-O-methylglucuronarabinoxylan, and 4-O-methylglucoarabinoxylan failed to form precipitates.

These results indicate that Gaillard's test<sup>2</sup> does not distinguish polysaccharides with a small number of single terminal branches from many linear polysaccharides. Polysaccharides with many filiform branches or with many terminal branches are not precipitated. Additional complications are introduced by the presence of carboxyl groups, the molecular weight of the polymer, and perhaps by the presence or absence of methylol groups on the anhydrosugar repeating units. The specificity of the reaction is influenced by the ionic nature of the solvent and by the nature of the halogen. In spite of its limitations, the test may be used under controlled circumstances to test for the presence of particular polysaccharides in mixtures, and if the hydrolytic and oxidative factors are eliminated or minimized, it may be used for preparative purposes.

### Origin of Type-III Porphyrins in Nature

A RECENT article by Marks<sup>1</sup> has reviewed the present state of knowledge concerning porphyrin biogenesis. A part of the pathway which has stimulated much speculation is the step involving the condensation of porphobilinogen (I) to uroporphyrinogen III, IV (iii). A good deal of information is available on the enzymes concerned. Briefly, it seems that two enzymes are involved, uroporphyrinogen-I-synthetase and uroporphyrinogen-III-co-synthetase. The first, when incubated with porphobilinogen (I), produces uroporphyrinogen I, IV (i), while in the presence of the second enzyme, the product is uroporphyrinogen III, IV (iii). Uroporphyrinogen I is not a substrate for the co-synthetase. (Ref. 1 gives a comprehensive bibliography.) Most attempts to explain this unusual cyclization have started from the assumption that the enzymes would utilize a pathway which could be illustrated by chemical condensations *in vitro*—and all have been criticized on the ground that they produce a mixture of porphyrin isomers of uncertain composition, whereas the enzymatic condensations are much more specific.

An interesting variant was recently suggested by Mathewson and Corwin<sup>2</sup> in which they proposed that a tetrapyrane (III) (with type I order of side-chains) was the key intermediate. The structure might fold in several ways to give, in different circumstances, uroporphyrinogen I or III or the vitamin B<sub>12</sub> chromophore. The weakness of this proposal is that it requires at least two of the pyrrole rings in (III) to be in the  $\alpha$ -pyrrolenine form, in order that the chain is sufficiently flexible. There is no evidence that pyrroles with the type of sub-

stitution required will exist in this form unless the nitrogen atom is protonated. The great merit of the proposal is that it focuses attention on the possible importance of stereochemistry in the cyclization.

Although the porphyrinogens are the important natural compounds, it is instructive to consider the symmetry of the porphyrins first.

The porphyrin ring is flat and hence all porphyrins have symmetry elements associated with the plane containing the macrocyclic system. However, the uroporphyrins, with the exception of type III, also have other symmetry properties. For example: type I, II (i) has a four-fold axis perpendicular to the plane of the ring, through the centre; type II, II (ii) has two planes of symmetry and a two-fold axis; type IV, II (iv) has one plane of symmetry. Thus, with the exception of the plane containing the porphyrin ring, uroporphyrin III, II (iii) is asymmetric and is the only uroporphyrin isomer with this property.

In the porphyrinogens, the bridging atoms each carry two hydrogens and the five-membered heterocycles are true pyrrole rings (IV). Consideration of models (Dreiding conformational models serve very well for this purpose) suggests that porphyrinogen rings are 'puckered'. Clearly, it should be possible to write the uroporphyrinogens types I, II and IV in forms which will retain all or some of the elements of symmetry outlined above for the corresponding porphyrins (though steric effects may place limitations on this in practice). For uroporphyrinogen III, however, there is no remaining element of symmetry.

Let us now arrange the molecules so that there is a minimum of interaction between the bridge CH<sub>2</sub> groups and the  $\beta$ -substituents. Assuming that the 'acetic' side-chain is the more bulky it is possible to arrange the mode

in such a way that the CH bonds of the meso-methylenes are staggered relative to the acetic side-chains. Thus we have a preferred conformation for the compound. The result is precisely similar if the 'propionic' side-chain is used; the only assumption necessary is that the two groups are not equally effective.

The simplest way to describe the conformation is to define the positions of the NH hydrogens as either 'up' or 'down' relative to the average plane of the macrocycle. Thus: (1) type I has two NH groups 'up' and two 'down' in a staggered sequence around the macrocycle; (2) type II has all four NH groups 'up' (or 'down'); (3) type IV has two NH groups 'up' on adjacent pyrrole rings and the other pair 'down'; (4) type III has three NH groups 'up' and one 'down'.

The purpose of this communication, therefore, is to suggest that uroporphyrinogen-III-co-synthetase has an asymmetric surface, perhaps with three necessary points of attachment, which can choose uroporphyrinogen III from a mixture.

It is now clear that chemical polymerization of monopyrroles (including porphobilinogen) to porphyrins generally produces mixtures of isomers. The composition of these mixtures has been the subject of some investigations<sup>3-5</sup> and the general conclusion is that acid-catalysed polymerization will produce mostly types III and IV and basic conditions will produce mostly type I (refs. 3, 4 and 6). A good deal has been written about the 'random' mixture of porphyrins produced from monopyrroles. This should give the isomers in the ratio I 1/8 : II 1/8 : III 1/2 : IV 1/4. It seems to me unlikely that such a random mixture could arise since the calculation of the ratio ignores the fact that the making and breaking of C—C bonds at the  $\alpha$ -positions of pyrroles is very dependent on the  $\beta$ -substituents. This is especially true in the series carrying the coproporphyrin side-chains ( $-\text{CH}_3$  and  $-\text{CH}_2\text{CH}_2\text{COOH}$  in the  $\beta$ -positions).

Thus, if uroporphyrinogen-I-synthetase, or part of its functional system, is a reversible deaminase enzyme (cf. ref. 7) which holds an equilibrium between porphobilinogen and a uroporphyrinogen mixture (plus ammonia in some form), then either the uroporphyrinogen I which has been prepared from this enzyme is not absolutely free of isomers or another part of the enzyme is concerned with removing uroporphyrinogen I from the mixture. The proportion of isomers in the uroporphyrinogen I need only be minute, provided that an equilibrium exists at the site of de-amination. Put in chemical terms, the de-amination is taking place under the equivalent of alkaline conditions.

To summarize, therefore, it is suggested that uroporphyrinogen-I-synthetase is a reversible de-amination enzyme which produces a mixture of isomers but with a very heavy preponderance of type I. The co-synthetase is a surface which picks out uroporphyrinogen III by its peculiar stereochemistry, thus forcing the equilibrium to give, finally, entirely the III isomer.

Several consequences of this hypothesis may be capable of experimental test.

(1) Uroporphyrinogen-I-synthetase may be a preparation with two distinct functions.

(2) The uroporphyrinogen I produced by this enzyme may not be absolutely homogeneous.

(3) The substrate for uroporphyrinogen-III-co-synthetase may be uroporphyrinogen-III itself and the enzyme may be capable of removing the isomer from a synthetic mixture.

(4) The stereochemical constraints postulated as governing the shape of porphyrinogen isomers must be large enough to be detected by chemical (or physical) techniques.

(5) The specificity of the enzymes after the formation of uroporphyrinogen III will decrease. The subsequent steps in the biogenesis of protoporphyrin IX all involve degradation of the side-chains which will then be less

effective in defining the conformation of the substrate. There is some evidence that this does occur, since all the uroporphyrinogens will form a coproporphyrin in the presence of the appropriate enzyme<sup>8</sup>. The specificity reappears with the enzyme responsible for the degradation of coproporphyrinogen III to protoporphyrin IX (ref. 9) and this may be the point at which the propionic side-chains take over the role of defining the conformation of the compound.

Attempts to determine the conformations of porphyrinogens have been initiated in this laboratory.

### Crystal Structure of Potassium Diperoxotricyanochromate(IV)

IN the course of an extensive investigation of peroxochromates the crystal and molecular structure of potassium diperoxotricyanochromate(IV),  $\text{K}_3[\text{Cr}(\text{O}_2)_2(\text{CN})_3]$ , has been solved by three-dimensional Fourier methods and refined five cycles by the structure factor least-squares method using 2076 reflexions. The  $R$ -factor has dropped to 0.123.

The unit cell dimensions were determined from rotation and Weissenberg photographs using  $\text{CuK}\alpha$  radiation. The unit cell is monoclinic with  $a = 11.52 \text{ \AA}$ ;  $b = 7.60 \text{ \AA}$ ;  $c = 12.13 \text{ \AA}$ ;  $\beta = 111.0^\circ$ .

The measured density was  $2.15 \text{ g cm}^{-3}$ , indicating the presence of four molecules per unit cell. The systematically absent reflexions were  $h0l$  with  $h = 2n + 1$ . This is characteristic of the space groups  $P2_1/a$  and  $Pa$ . An intensity distribution curve revealed the presence of high symmetry and  $P2_1/a$  was therefore chosen. During the structure investigation it became obvious that a plausible structure could be obtained based on this assumption.

The structure investigation shows that chromium has co-ordination number seven and that the geometrical configuration of the ligands is a pentagonal bipyramid. The O—O bond distances are  $1.440 \pm 0.012 \text{ \AA}$  and  $1.455 \pm 0.012 \text{ \AA}$ , close to values found in  $[\text{Cr}(\text{O}_2)_2(\text{NH}_3)_3]$  (1).  $[\text{CrO}(\text{O}_2)_2\text{py}]$  (2–4) and in  $\text{K}_3[\text{Cr}(\text{O}_2)_4]$  (5). The four Cr—O bond lengths range from  $1.871 - 1.902 \text{ \AA}$  (e.s.d.  $0.009 \text{ \AA}$ ), and the three Cr—C bond lengths from  $2.081 - 2.102$  (e.s.d.  $0.012 \text{ \AA}$ ). The mean value of the carbon–nitrogen bond distances is  $1.137 \text{ \AA}$  (e.s.d.  $0.018 \text{ \AA}$ ) ( $1.15 \text{ \AA}$  is usually found in cyanide groups).

The complex ion  $[\text{Cr}(\text{O}_2)_2(\text{CN})_3]^{3-}$ , therefore, is built in the same fashion as  $[\text{Cr}(\text{O}_2)_2(\text{NH}_3)_3]$  (1,6) with the cyanide groups replacing the ammonia groups.

### Electrical Resistivities and the Type of Bonding in Some Quinone Complexes

MOST molecular complexes are essentially of the non-bonding type and their infra-red spectra are quite similar to the superposed spectra of the components<sup>1,2</sup>. However, the infra-red spectra of some diamine-quinone complexes and azine-quinone complexes have been found to show the pattern of the semiquinone ion instead of the quinone. Such complexes have been characterized as essentially of the dative type. Thus charge transfer molecular complexes may be classified into two groups, namely, the non-bonding type and the dative type, based on their infra-red spectra. Using this method of classification, I have pointed out that most of the known complexes having resistivities of  $10^6$  ohm cm or less are of the dative type<sup>3</sup>.

In addition to those reported in ref. 3 there are many complexes which are semiconducting or which are likely to be semiconducting but for which only the electrical resistivity or the infra-red spectrum has been reported. Hoping to find a relation between the electrical resistivity and the type of bonding in these complexes, I have measured the necessary properties. Nearly all of the known and some new complexes of *p*-chloranil, *p*-bromanil, 2,3-dichloro-5,6-dicyano-*p*-benzoquinone and its bromo analogue exhibiting resistivities of  $10^{11}$  ohm cm or less are included in the present work. These quinones and their semiquinone ions show infra-red spectra sufficiently different from each other for characterization of the complexes<sup>3</sup>.

Measurements of the electrical resistivities were made on compressed samples. The infra-red spectra were recorded as mineral oil mulls using a Perkin-Elmer Infracord spectrophotometer. The results are summarized in Table 1. The complexes are presented in the order of increasing resistivity. If two or more different resistivity values are available for the same complex, the lowest value is taken for this purpose. The quinones are indicated by the kind and number of the substituents: for example, Cl<sub>4</sub> for *p*-chloranil and Cl<sub>2</sub>Cy<sub>2</sub> for 2,3-dichloro-5,6-dicyano-*p*-benzoquinone. The mole ratio of acceptor to donor is given only when the ratio is known to be different from 1:1. Most of the others are of 1:1 composition, but some are of unknown composition. The infra-red spectra are classified by the pattern due to the acceptor component: Q indicates the pattern of quinone molecule and SQ indicates the pattern of semiquinone ion. In none of the cases examined was the co-existence of the quinone and the semi-quinone ion observed.

As reported before, the anomalously composed dibenzo [c,d] phenothiazine complexes, Nos. 1 and 3, are much more conducting than the corresponding 1:1 complexes, Nos. 7 and 29. All of them are of the dative type<sup>4</sup>.

It is rather surprising to find that the highly conducting 1,6-diaminopyrene complexes, Nos. 4 and 5, are of the non-bonding type. Kronick *et al.* have reported that the spectra of these two complexes in the visible region are characteristic of a large radical-ion component. Comparing the observed spectra with the computed spectra for mixtures of free components and radical ions, they estimated the mole fraction of ionic component for the complexes as 0.65 with *p*-bromanil and 0.90 with *p*-chloranil. It was concluded that the

presence of large amounts of the oxidized and reduced forms of amine-quinone complexes appears to correlate with high conductivity<sup>5</sup>. The present characterization by infra-red spectra, however, does not support such a conclusion. Contrary to the high fractions of ionic component estimated by Kronick, these 1:1 complexes are of the non-bonding type. For example, the spectrum of the *p*-chloranil complex given in Fig. 1 is close to the superposed spectra of the neutral components.

Kronick *et al.* have reported that the diaminopyrene-dichlorodicyano-*p*-benzoquinone complex, No. 2, is about

Fig. 1. Infra-red spectra of the 1,6-diaminopyrene-*p*-chloranil complex (top) and the component compounds (bottom), 1,6-diaminopyrene (—) and *p*-chloranil (-----)

95 per cent ionic. The infra-red spectrum indicates the dative nature of the bonding and is consistent with their conclusion.

In the case of the other diamine complexes, *p*-phenylene-diamine and its derivatives are known to form complexes of the dative type<sup>3</sup>; however, tetramethylbenzidine and 1,5- and 1,8-diaminonaphthalenes were found to give complexes of the non-bonding type, Nos. 24, 27, 31 and 37.

Most of the complexes with resistivities of 10<sup>7</sup> ohm cm or higher were found to be of the non-bonding type; there are two exceptions, namely, Nos. 29 and 32. Therefore, we must conclude that bonding of the dative type is neither necessary (Nos. 4 and 5), nor enough (Nos. 29 and 32), for the appearance of low resistivity in molecular complexes.

It is apparent that intermolecular interaction extended, at least one-dimensionally, throughout the crystal is required for transport of electrons or holes. In our semi-conducting molecular complexes such interaction may be provided by a strong charge ( $\pi$ -electron) transfer force. As mentioned above, the resulting complex does not need to be dative. Although the infra-red spectrum appears to be useful and reliable in classifying the type of bonding in molecular complexes, the spectrum does not give any information on how strong the interaction is. Consequently it may be possible that the charge transfer interaction in some complexes essentially of the non-bonding type is stronger than that in some complexes essentially of the dative type. Moreover, we do not obtain by the infra-red spectrum information as to whether the interaction is limited to within a pair of donor and acceptor molecules or extended farther. Perhaps, in the complexes of the dative type but with relatively high resistivities the interaction between donor and acceptor molecules may be only local or ionic rather than dative.

I wish to thank Dr. G. A. Castellion for his advice.

## Evaluation of Diffusion Coefficients in Free-boundary Diffusion Experiments

IN free-boundary diffusion experiments a boundary between two solutions of different concentrations is formed in a cylindrical cell and the evolution with time of the concentration distribution is examined. For the evaluation of the diffusion coefficient from the experimental data several methods are available, for example, the moment method and the area method. In these methods the existence of an initially sharp boundary between the two solutions is in general presumed. However, it will be shown that the moment method is valid for very general boundary conditions, a fact that seems to have been overlooked in the past.

The second moment  $m_2$  of the normalized concentration distribution is defined by the equation:

$$m_2 = \frac{1}{\Delta c} \int_{-\infty}^{\infty} x^2 \frac{dc}{dx} dx \quad (1)$$

The time derivative of  $m_2$  may be written:

$$\frac{dm_2}{dt} = \frac{1}{\Delta c} \frac{d}{dt} \int_{-\infty}^{\infty} x^2 \frac{dc}{dx} dx = \frac{1}{\Delta c} \int_{-\infty}^{\infty} x^2 \frac{\partial}{\partial x} \left( \frac{\partial c}{\partial t} \right) dx \quad (2)$$

where it is assumed that the last integral is uniformly convergent and that:

$$\frac{\partial^2 c}{\partial t \partial x} = \frac{\partial^2 c}{\partial x \partial t} \quad (3)$$

From equation (2) and the diffusion equation (4) (in which  $D$  may be a function of the concentration):

$$\frac{\partial c}{\partial t} = \frac{\partial}{\partial x} \left( D \frac{\partial c}{\partial x} \right) \quad (4)$$

one obtains on partial integration:

$$\frac{dm_2}{dt} = \frac{1}{\Delta c} \int_{-\infty}^{\infty} x^2 \frac{\partial^2}{\partial x^2} \left( D \frac{\partial c}{\partial x} \right) dx = \frac{1}{\Delta c} \left\{ \int_{-\infty}^{\infty} x^2 \frac{\partial}{\partial x} \left( D \frac{\partial c}{\partial x} \right) - 2 \int_{-\infty}^{\infty} x D \frac{\partial c}{\partial x} + 2 \int_{-\infty}^{\infty} D \frac{\partial c}{\partial x} dx \right\} \quad (5)$$

For well-behaved functions the integrated parts in (5) vanish and one obtains:

$$\frac{dm_2}{dt} = \frac{2}{\Delta c} \int_{-\infty}^{\infty} D \frac{\partial c}{\partial x} dx = 2\bar{D} \quad (6)$$

where  $\bar{D}$  is the mean diffusion coefficient. Integration of (6) gives finally:

$$\bar{D} = \frac{m_2(t) - m_2(0)}{2t} \quad (7)$$

Thus, the moment method is valid for an initial concentration distribution satisfying the very general conditions mentioned above (equation (3) and conditions for integration in (2) and (5)) and, in the case of concentration dependent diffusion, yields the mean value<sup>1,2</sup> of the diffusion coefficient over the concentration interval investigated.

## Cleavage of *o*-Nitrophenylsulphenamides by Raney Nickel and Applications for Peptide Synthesis\*

THE *o*-nitrophenylsulphenyl (NPS) residue has recently been introduced as an amine-protecting group for amino-acids and peptides during peptide synthesis by Zervas *et al.*<sup>1</sup> It is readily cleaved by mild acidolysis using 2-3 equivalents of hydrochloric acid in ether. Although this treatment allows the selective cleavage of the *o*-nitrophenylsulphenamide group in the presence of acid-labile *tert*-butylesters in the peptide moiety under carefully controlled conditions<sup>2</sup> another cleavage procedure avoiding the use of acid altogether might prove useful.

It has now been found that desulphuration by rancy nickel<sup>3</sup> provides a convenient procedure for the selective

Preparation from NPS-amino-acids and *N*-hydroxysuccinimide using dicyclohexylcarbodiimide.

removal of the *N*-*o*-nitrophenylsulphenyl group from peptides. The cleavage of the sulphenamide is easily accomplished by passing a solution of an NPS-peptide derivative in an organic solvent through a raney nickel column at room temperature. Any danger of an unwanted partial cleavage of the very useful acid labile *N*-*tert*-butoxycarbonyl<sup>4</sup>, *tert*-butylester<sup>5</sup>, *tert*-butylether<sup>6</sup>, or amine-protecting groups from β-dicarbonyl derivatives<sup>7</sup> is thus avoided. Other common protecting groups are also left intact, for example, alkylesters, *N*-toluenesulphonyl, *N*-triphenylmethyl, *N*-trifluoroacetyl, and *N*-formyl groups. (The benzyloxycarbonyl (Z) group is cleaved (reductively) by passing solutions of Z-peptides in similar manner through raney nickel columns.) For the preparation of NPS-peptide derivatives and for the stepwise elongation of the peptide chain *N*-hydroxysuccinimide esters<sup>8</sup> of NPS-amino-acids have been found to be useful reagents which on addition to eluates of raney nickel columns give the corresponding homologue NPS-peptides in high yields within a few hours at room temperature. Fig. 1 shows schematically the synthesis of NPS-Gly-Pro-Ala-Thr-OMe. In similar manner NPS-Gly-Pro-Ala-Thr(Bu<sup>t</sup>)-OBu<sup>t</sup>, NPS-Pro-Ala-Ser(Bu<sup>t</sup>)-OBu<sup>t</sup>, and Z-Leu-Val-Glu(OBu<sup>t</sup>)-Ala-N<sub>2</sub>H<sub>2</sub>BOC have been synthesized. Table 1 presents data of *o*-nitrophenylsulphenyl-amino-acid-*N*-hydroxysuccinimide esters. Two typical examples serve to outline the experimental details.

Example *a*: *o*-Nitrophenylsulphenyl-L-prolyl-L-alanyl-L-threonine methylester (1.14 g = 2.5 m.moles): [f.p. 159°-160°, [α]<sub>D</sub><sup>25</sup> = -105.0° (c 1, ethanol)] was dissolved in dimethylformamide (5 ml.) and placed on a raney nickel *W* 5 (ref. 10) column (2 cm × 5 cm) which had previously been washed with the same solvent. When the yellow solution was absorbed the column was washed with dimethylformamide (approximately 100 ml.) at a flow rate of about 30 ml./h until the colourless effluent was ninhydrin negative. (Raney nickel preparations which tended to pack too tightly in the column due to particle size were mixed with 10-30 per cent 'Hyflo Super Cell' in order to allow a reasonable flow rate.)

Fig. 1. Synthesis of sequence 153-158 of tobacco mosaic virus (vulgare) protein<sup>9</sup>. (NPS, *o*-nitrophenylsulphenyl; OSu, *N*-hydroxysuccinimide ester, DCCI, dicyclohexylcarbodiimide)

The eluate contained L-prolyl-L-alanyl-L-threonine methylester in paper chromatographically pure form (*R<sub>F</sub>* 0.35 in *sec*-butanol/formic acid/water, 75:13.5:11.5). *o*-Nitrophenylsulphenyl-glycine-*N*-hydroxy-succinimide ester (0.82 g = 2.5 m.moles) was added. After standing for 4 h at 20° C the solvent was removed *in vacuo*, the residue reprecipitated from ethanol/water (5:100 ml.), filtered off and washed successively with 1 M citric acid, 1 M sodium hydrogen carbonate and water. On drying 1.25 g (98 per cent) crystalline crude material were obtained. Recrystallization from ethanol/water gave 1.09 g (85 per cent) *o*-nitrophenylsulphenylglycyl-L-prolyl-L-alanyl-L-threonine methylester, f.p. 193°-195°, [α]<sub>D</sub><sup>25</sup> = -100.0° (c 1, ethanol), C<sub>21</sub>H<sub>20</sub>N<sub>2</sub>O<sub>8</sub>S (511.5); calc. C 49.3, H 5.71, N 13.7, S 6.28; found C 49.2, H 5.79, N 13.7, S 6.28.

Example *b* (essentially the same procedure was used as in example *a*): *o*-Nitrophenylsulphenyl-L-alanyl-*O*-*tert*-butyl-L-threonine-*tert*-butylester (6.0 g = 13.2 m.moles) [f.p. 110°-112°, [α]<sub>D</sub><sup>25</sup> = -35.0° (c 1, ethanol)] in 25 ml. dimethylformamide. Raney nickel column size: 5.5 cm. × 6.0 cm. Elution with approximately 1,000 ml. dimethylformamide. Reaction with *o*-nitrophenylsulphenyl-L-prolin-*N*-hydroxysuccinimide ester (4.8 g = 13.2 m.moles). 7.2 g (98.5 per cent) crude product, f.p. 142°-144°. Recrystallization from ether/hexane gave 6.86 g (94 per cent) *o*-nitrophenylsulphenyl-L-prolyl-L-alanyl-*O*-*tert*-butyl-L-threonine-*tert*-butylester, f.p. 145°-147°, [α]<sub>D</sub><sup>25</sup> = -83.8° (c 1, ethanol), C<sub>26</sub>H<sub>40</sub>N<sub>4</sub>O<sub>8</sub>S (552.7); calc. C 56.5, H 7.30, N 10.1, S 5.80; found, C 56.5, H 7.21, N 10.3, S 5.73. When NPS-Ala-Thr(Bu<sup>t</sup>)-OBu<sup>t</sup> was cleaved by three equivalents of hydrochloric acid in ether<sup>1</sup> not more than 60 per cent H-Ala-Thr(Bu<sup>t</sup>)-OBu<sup>t</sup> could be isolated (due to its solubility in most solvents).

With the procedure described many peptides can be prepared in a simple manner, except those with sulphur-containing amino-acids (Cys, Met). The reaction times are short (a few hours), the isolation of the products is easy and the yields are good. The complete removal of the *o*-nitrophenylsulphenyl group is easily visible from a colourless effluent of the raney nickel column. The quantitative elution of the peptide derivative requires relatively large volumes of solvent, which is a slight disadvantage. For the preparation of small peptides the raney nickel procedure seems to offer advantages over the acidolytic cleavage of the NPS-group in (a) giving higher yields and (b) providing an additional selective procedure that leaves intact other acid labile groups present in the peptide moiety. In several instances the procedure proved to be even superior to hydrogenation of the corresponding benzyloxycarbonyl-peptides in giving higher yields. Comparison of two Z-Pro-Ala-Thr-OMe preparations, one synthesized by the procedure described in this communication using NPS-Ala-Thr-OMe and Z-Pro-OSu<sup>8</sup> and the other starting from Z-Ala-Thr-OMe which was catalytically hydrogenated, gave identical melting points and optical rotations.

I thank Dr. habil. H. A. Offe and Dr. E. Schnabel for their advice. This work was supported by Farbenfabriken Bayer A.G., Wuppertal-Elberfeld.

## BIOCHEMISTRY

### Radioisotope Investigation of the Effect of Sunlight on Beer

THE formation of mercaptan on exposing beer to sunlight has been recognized for many years. It has also been shown that the mercaptan develops parallel with the occurrence of the sunlight flavour<sup>1,2</sup>. In the early report from this laboratory, according to the results of various model experiments with humulone and lupulone analogues, it was suggested that the flavour substance is a kind of mercaptan, especially prenyl mercaptan (3-methyl-2-butenyl-1-thiol)<sup>3,4</sup>. Kuroiwa *et al.*<sup>5</sup> have detected 3-methyl 2-butenyl mercaptan in 'sunstruck' beer as its 2,4-dinitrophenyl derivative by a chromatostrip method, and proposed isohumulones as the sole precursor of this mercaptan because when isohumulones in the model solution were replaced by humulones, lupulones and other related compounds, no 'sunlight' flavour could be detected.

The evaluation of sunlight flavour of beer has long been carried out only by organoleptic test. A potentiometric method has recently been proposed by Kuroiwa *et al.*<sup>5</sup>. However, the sensitivity of this method was limited by contaminant materials that were driven out from beer and consumed silver ions. When an air-injected beer bottle was exposed to the sunlight, Kuroiwa *et al.* observed that the amount of substances consuming silver ions increased markedly, but the odour was entirely different from the so-called 'sunstruck' beer.

The experiments reported here were initiated as an attempt to determine the precursors of mercaptan with the aid of compounds labelled with sulphur-35. It has now been shown that sodium sulphide is more active than cysteine in serving as the sulphur source of mercaptan.

The radioactive sulphur compounds were purchased from the Radiochemical Centre, Amersham, England. The humulones used were prepared by Mr. Haruo Tanaka. Lupulones, acetolupuphenone synthesized by Riedl's method<sup>6</sup>, and isohumulones prepared according to the procedure of Carson<sup>7</sup> were gifts of Dr. Mitsuo Koshika. L-Cysteine-<sup>35</sup>S was prepared by the reduction of L-cysteine-<sup>35</sup>S with tin-hydrochloric acid. 3-Methyl 2-butenyl mercaptan (b.p. 125°-127°) was synthesized from 3-methyl 2-butenyl bromide and thiourea<sup>8</sup>.

To 20 mg of humulones dissolved in 7 ml. ethyl alcohol was added 180 ml. of water saturated with carbon dioxide at 0° C and a solution of the sulphur-35 compound (0.01

Table 1. EFFECT OF COMPOUNDS ON THE INCORPORATION OF SULPHUR-35 INTO MERCAPTAN

Expt.	Compounds tested	Sulphur source	Total radioactivity in 2,4-dinitrophenyl deriv. (c.p.m.)
1	Humulones	Na <sub>2</sub> S	7,800
	Lupulones	Na <sub>2</sub> S	3,075
	Humulones	Cysteine	725
	Lupulones	Cysteine	425
2	Humulones	Na <sub>2</sub> S	6,625
	Lupulones	Na <sub>2</sub> S	1,825
	Isohumulones	Na <sub>2</sub> S	6,275
	Acetolupuphenone	Na <sub>2</sub> S	7,125

m.mole,  $1 \times 10^5$  c.p.m.). The mixture was bottled in colourless transparent bottles and exposed to direct sunlight. After the addition of 50 mg of prenyl mercaptan dissolved in 10 ml. of ethyl alcohol, the solution was extracted continuously with diethyl ether. The extract was washed, dried and finally concentrated to a small volume. A mixture of sodium bicarbonate (500 mg), 2,4-dinitrofluorobenzene (100 mg), acetone (20 ml.), and water (20 ml.) was added to the concentrate and kept in dim light at room temperature for about 24 h. The derivatives were extracted with benzene, and the benzene layer was thoroughly washed with 2 N sodium hydroxide to remove humulones and other phenol compounds and also the 2,4-dinitrophenyl derivative of hydrogen sulphide. The benzene solution was washed with water, dried and concentrated to 25 ml. 1 ml. (about 3 mg of the derivatives) of this solution was used for the determination of radioactivity.

A comparison of sodium sulphide S-35 and cysteine S-35 as precursors is presented in Table 1. When compared with humulones, isohumulones or acetolupuphenone, lupulone is a poor precursor of mercaptan. To obtain high incorporation of radioactivity into mercaptan, saturation with carbon dioxide was necessary; its omission caused a 50 per cent decrease in incorporation. Addition of vitamin C resulted in failure to obtain significant increase of sulphur-35 incorporation into mercaptan. These results are summarized in Table 2.

Table 2. EFFECT OF CARBON DIOXIDE AND VITAMIN C ON INCORPORATION OF SULPHUR-35 INTO MERCAPTAN

Saturation with carbon dioxide	Vitamin C (10 mg/180 ml.)	Total radioactivity in 2,4-dinitrophenyl deriv. (c.p.m.)
+	-	10,975
-	-	5,375
-	+	6,850
+	+	11,525

Kuroiwa *et al.*<sup>5</sup> considered isohumulones as the sole precursor of mercaptan. However, our experimental results, shown in Table 1 (Experiment 2), are entirely different.

It seems likely that light induces the formation of the prenyl radical or of a free radical intermediate by the abstraction of hydrogen from the carbon neighbouring the double bond of the prenyl chain in the molecule of humulones. Prenyl mercaptan might be formed by the combination of the prenyl radical and thiol radical initiated from hydrogen sulphide, cysteine, or glutathione. Also, this mercaptan can be formed by the fission of a thiol compound, probably produced by the combination of a thiol radical and a humulone free radical as described here. This is also possible in the case of isohumulones, acetolupuphenone, and lupulones.

### Action of Non-penetrating Heavy Metals on the Catalase Activity of Yeast Cells

THE catalase activity of intact yeast cells which is 'patent' (that is, active *in vivo* against external substrate) is biologically distinct from the activity which is 'cryptic' (that is, hidden within the cell, detectable only after lysis of the cell). This conclusion followed from the demonstration that the cryptic enzyme was far more heat-labile than the patent fraction<sup>1</sup>.

Yeast catalase is an inducible enzyme<sup>2,3</sup>, its inducer being either oxygen or possibly  $\text{H}_2\text{O}_2$  formed by endogenous reduction of oxygen. When fully induced originally aerobic yeast was grown in anaerobiosis, the cryptic activity of the cell diminished due to dilution; the specific patent activity remained constant for one or more generations, due to flow of enzyme from the cryptic to the patent fraction<sup>4</sup>.

In order to account for these observations, I proposed a hypothesis which in its general form assumed that the patent enzyme was fixed at sites in the cell membrane, with its active centres available to external substrate, and stable to heat by virtue of being membrane-bound<sup>1</sup>. In a more specific form, the membrane model assumed that an equilibrium existed between the membrane-bound patent fraction and the cryptic fraction; mass action determined the level of patent activity for any given internal concentration of enzyme<sup>4</sup>.

In a series of elegant investigations begun in 1948<sup>5</sup>, Rothstein and his colleagues have investigated the nature of the binding to intact yeast cells and the physiological effects of a variety of heavy metals<sup>6-8</sup>. Of particular interest was his demonstration that uranyl ion ( $\text{UO}_2^{2+}$ ) inhibited both the fermentation of exogenous (but not endogenous) glucose and the activity of invertase (which in yeast is membrane-bound<sup>9,10</sup>) by binding to ligands in the cell membrane; this ion could not penetrate to the cell interior<sup>11</sup>. For example, disruption of the membranes of yeast increased by about 100 times the maximum binding of  $\text{UO}_2^{2+}$  by a yeast suspension<sup>9</sup>. Rothstein also showed that mercuric ion at low concentration was bound to membrane ligands, without appreciably modifying membrane permeability. At mercury concentrations of  $10^{-4}$  M and higher, the permeability characteristics of the membranes altered, as shown by their leakiness to intracellular potassium, and to external dyes. These observations suggested a test of the hypothesis that the patent catalase of aerobic yeast was membrane-bound; if so, it should be possible to inhibit this activity by non-penetrating heavy metals.

In these experiments, I used the same commercial brand of bakers' yeast (standard brands) as did Rothstein. Tris buffer at pH 5.1 was used routinely. Catalase activity was assayed by the titanium method<sup>12</sup>, with a final  $\text{H}_2\text{O}_2$  concentration of 0.02 M; yeast concentration in the assay was about 4 mg/ml. When uranyl ion was tested, it was included in the assay mixture. The effect of mercury was examined by pre-treating the cells with  $\text{HgCl}_2$ , usually at a concentration of  $8 \times 10^{-5}$  M, and then twice washing them with buffer before assay; aliquots of the mercury-treated and control cells were also treated with *n*-butanol prior to assay<sup>13</sup>, in order to determine the effect of mercury on the cryptic enzyme.

The effect of varying concentrations of  $\text{UO}_2^{2+}$  on patent activity is shown in Fig. 1, Curve A, and on that of lysed cells in Curve B. The patent activity was virtually abolished at a concentration of 0.1 M, whereas the enzyme of the butanol-lysed cells was completely inactivated at  $5 \times 10^{-4}$  M  $\text{UO}_2^{2+}$ , and was thus about 500 times more sensitive. The inhibition of patent activity could be reversed to some extent by high substrate concentration, as shown in Fig. 2, Curve A, but that of the lysed cells could not (Curve B). Since the latency of intracellular yeast catalase has been attributed to impermeability of the membrane to  $\text{H}_2\text{O}_2$  (ref. 14), it would

Fig. 1. The effect of concentration of uranyl ion on the patent catalase activity (Curve A) and the catalase activity of butanol-lysed cells (Curve B).

Fig. 2. The effect of concentration of  $\text{H}_2\text{O}_2$  on the inhibition of patent (Curve A) and lysed cell (Curve B) catalase activities caused by  $0.1 \text{ M } \text{UO}_2^{2+}$ .

seem that the site of reversal of the inhibition was at the cell membrane. The inhibition of patent activity by  $\text{UO}_2^{2+}$  could also be partly reversed (about one-third) by the subsequent addition of 0.05 M ethylenediamine tetraacetic acid to the assay mixture; this poly-carboxylic acid is unlikely to penetrate the yeast cell. Furthermore, the inhibition of patent activity could be reversed to a similar extent by  $5 \times 10^{-3}$  M inorganic phosphate in the assay; yet Rothstein has shown that the cytoplasm of this strain of commercial yeast contained inorganic phosphate at a concentration of  $10^{-2}$  M (ref. 6). Thus, the inhibition of patent catalase by  $\text{UO}_2^{2+}$ , and its partial reversal by high  $\text{H}_2\text{O}_2$ , by EDTA and by inorganic phosphate all suggest localization of the patent enzyme at the cell surface.

The effect of pre-treating yeast with varying concentrations of mercury prior to assay is shown in Fig. 3; the ordinate represents the ratio of mercury-treated cells: control cells. Thus a value greater than 1 indicates that mercury has increased the activity of the suspension, and a value less than 1 indicates an inhibition. Curve A shows that the patent activity was inhibited by concentrations of mercury of  $10^{-4}$  M and lower. At somewhat higher concentrations ( $3 \times 10^{-4}$  M to  $10^{-3}$  M) the activity of the treated cells was considerably higher than that of the controls. In this range of concentration of  $\text{Hg}^{2+}$ , the measured activity was the resultant of two competing effects of the heavy metal: (1) The activity of some cells was increased, due to the binding of mercury by certain membrane ligands, permitting increased permeability to  $\text{H}_2\text{O}_2$ , but not allowing entrance of the mercury itself. (2) Above a threshold amount of membrane-bound mercury, the total inactivation of both the cryptic and patent catalases of most of the cells occurred as the membranes became permeable to the mercury<sup>6</sup>. Since lysis induced by an agent (like butanol) which does not inactivate the enzyme results in a 60-fold increase in activity of the suspension<sup>1,4</sup>, it is clear from the observed 2- to 3-fold

Fig. 3. The effect of concentration of  $\text{HgCl}_2$  on the catalase activities of A, intact cells, and B, lysed cells. Ordinate: ratio of activities of suspensions pre-treated with mercury: control suspensions

increase that both processes were occurring simultaneously but that the second was predominant. At concentrations of mercury higher than  $10^{-2}$  M, all activity was destroyed; the previously cryptic enzyme had also been completely inactivated as shown by subsequent lysis of the treated cells with butanol. Thus butanol could not reverse the inhibition of catalase by mercury.

Table 1. EFFECT OF MERCURY PRE-TREATMENT ON PATENT AND CRYPTIC CATALASE ACTIVITY

Intact cells were treated with  $8 \times 10^{-5}$  M  $\text{HgCl}_2$  (or in a few cases  $10^{-4}$  M) and twice washed with buffer. Their catalase activity was then assayed either directly or after treatment with butanol to expose the cryptic enzyme. Standard deviations are shown

A. Data from 15 out of 22 expts.; inhibition of patent activity > 15%:	
% Inhibition before butanol	% Inhibition after butanol
$29.1 \pm 8.0$	$1.4 \pm 3.8^*$
B. Data from all 22 experiments:	
% Inhibition before butanol	% Inhibition after butanol
$23.4 \pm 10.9$	$2.7 \pm 4.6^*$

\* Not significantly different from zero.

Table 1 summarizes the results of a series of experiments in which yeast suspensions were pre-treated with either  $8 \times 10^{-5}$  M, or  $10^{-4}$  M,  $\text{Hg}^{2+}$ , washed and then assayed either directly or after lysis. Inhibition of the patent catalase was of the order of 25 per cent; on the other hand, the cryptic enzyme was inhibited by only about 2 per cent, and this inhibition was statistically insignificant. Even if one were able to inhibit the patent activity completely, the activity of the butanol-treated cells, which increased by a factor of about 60 after lysis, would be inhibited by only about 2 per cent, which would not be detected by this method of assay. Several experiments similar to those described in Table 1 were performed on the patent catalase of anaerobically-grown, catalase-poor yeast; no inhibition of their patent activity could be detected at a mercury concentration of  $10^{-4}$  M.

The much greater resistance of the patent catalase to uranium (Fig. 1) is reminiscent of the finding<sup>15</sup> that the membrane-bound invertase of intact yeast was about 200 times more resistant to silver than was the extracted, purified enzyme. This has been interpreted as being due to preferential binding of the silver to inert membrane ligands with greater affinity for the metal<sup>16</sup>. But the catalase of the lysed cells, although immersed in a sea of exposed metal-binding groups of cell proteins and nucleic acids, etc., was extremely sensitive to uranium. Thus there exists the possibility that patent enzymes were stabilized against conformational changes by virtue of the way in which they were bound to the membrane. A possibly similar phenomenon was found in the case of a membrane-bound transport system for  $\beta$ -glucosidase in yeast, which was far more resistant to mercury than was

the  $\beta$ -glucosidase of lysed cells, despite the fact that the affinities of both transport system and enzyme for substrate and competitive inhibitors were identical<sup>17</sup>. Binding of crystalline liver catalase to various model surfaces was found to modify certain of its enzymatic properties<sup>18</sup>, so that it seems not unreasonable that membrane binding might alter the sensitivity of proteins to heavy metal inhibition.

It is therefore concluded that: (1) Uranyl ion, which has been found not to penetrate the cell membrane, could completely inhibit the patent catalase activity of yeast; the inhibition could be partly reversed by external inorganic phosphate at a concentration considerably lower than that which exists in yeast cytoplasm. The inhibition was also partly reversible by EDTA and by high substrate concentration. (2) Mercuric ion caused a significant inhibition of patent activity under conditions in which it was unable to penetrate the cell membrane, as shown by the fact that the cryptic enzyme was fully active, when assayed following lysis of the mercury-treated cells. (3) The patent catalase activity of aerobic yeast is due to enzyme molecules held at the cell membrane, or external to it in the cell wall.

I thank Mrs. Wanda Tacreiter for expert assistance, and the Medical Research Council of Canada for continued support of my work.

## Keratin Protofilaments and Ribosomes from Hair Follicles

SEVERAL proteins, fibrous and non-fibrous, differing in morphology and chemistry, are synthesized by the hair follicle, not only in the hair itself, but also in the closely-associated inner root sheath<sup>1</sup>. Work on these proteins, particularly with regard to the distribution of the amino-acids cystine and citrulline, requires the development of an *in vitro* system similar to that used in the investigation of protein synthesis in a variety of other tissues<sup>2</sup>. We wish to report the practicability of such an approach for hair follicles.

Hair follicle tissue from the skin of albino guinea-pigs 8-15 weeks old was obtained by the wax method<sup>1,3</sup> and by this procedure the 'dispersed' tissue was brought together in an amount sufficient for investigation. Homogenization in a Potter-Elvehjem homogenizer was carried out for periods of 5-10 sec in a basic medium containing  $\text{tris-Mg}^{2+}$ -KCl. Sucrose was included when

necessary. Fractions were obtained by centrifugation at increasing  $g$  values, namely, 350 $g$ ; 10,000 $g$ ; 30,000 $g$  and 105,000 $g$ , and were examined by electron microscopy of sections and by negative-staining.

The material sedimented at low  $g$  values contained a high proportion of keratin fibrils. Protofilaments (formerly termed protofibrils<sup>4</sup>) of about 20 Å diameter were present and the proportion of these structures was markedly increased by brief ultrasonication in the presence of 90 per cent formic acid as swelling agent, a procedure which liberates them from the 80 Å-diameter keratin filaments (formerly termed microfibrils<sup>4</sup>, Fig. 1). The identification of these structures in the hair follicle fractions strongly supports the view, put forward from electron microscopy of sectioned  $\alpha$ -keratins, that 80 Å-diameter keratin filaments consist of a number (possibly 10 or 11) of protofilaments 20 Å in diameter<sup>5-7</sup>. This visualization of protofilaments is, therefore, contrary to recent claims that they are not real structures<sup>8-10</sup>. The protofilaments probably consist of 2 or 3 protein chains with a high  $\alpha$ -helical content<sup>11</sup>. Keratin synthesis presumably involves the formation of these elements followed by their aggregation into larger filaments and then fibrils, this last stage requiring the incorporation of the matrix protein.

In the evaluation of the contents of fractions obtained at higher  $g$  values, it has not been possible, so far, to obtain evidence of intact mitochondria; presumably the homogenizing conditions used (which included sucrose), and the effect of fibrous keratin during homogenizing, did not prevent disruption of the mitochondria. Material sedimented at 30,000 $g$  contained 'free' ribosomes and 'smooth' membranes. Typical microsome fractions would not be expected and were not found, because hair follicle cells have a cytoplasm rich in ribosomes, but virtually lacking in endoplasmic reticulum. At 105,000 $g$ , pellets were obtained, which, on examination in the electron

Fig. 3. Ribosomes sedimented at 105,000 $g$  shadowed with platinum ( $\times 80,000$ )

microscope, were found to consist entirely of ribosomes about 150 Å in diameter and presumably of the 70s type (Figs. 2 and 3).

When subjected to centrifugation on sucrose density-gradients, the optical density profiles of the ribosome fractions indicated the presence of polysomes. Moreover, we have found that the 105,000 $g$  supernatants will activate amino-acids and incorporate them into  $s$ -RNA (transfer-RNA) prepared from hair follicle tissue by the phenol method<sup>12</sup>. These results suggest that it should be possible to subject the hair follicle to a full investigation of protein biosynthetic pathways.

### Characterization of Plant Pigments by Gas Chromatography

PLANT pigments are compounds which are not volatile at the temperatures normally used in gas chromatography (up to about 250° C). The only reported work in this field has been carried out using the methyl esters of flavonoid compounds<sup>1</sup>. In this work characterization of the pigments was attempted by the technique of analysis of the products of pyrolysis. The original design of the apparatus used for this work was described for the analysis of phenolic resins and rubber polymers<sup>2</sup> and has since found many applications including the characterization of non-volatile alkaloids<sup>3</sup>, polystyrene<sup>4</sup>, purines and pyrimidines<sup>5</sup> and barbiturates<sup>6</sup>.

The apparatus used in this work was the Pye 'Panchromatograph' fitted with a 5-ft. column in which the stationary phase was silicone oil (20 per cent) supported on 'Celite'. The detector was the macro-argon type maintained at a potential of 500 V and the argon carrier gas flow was 60 ml./min at an inlet pressure of 20 lb./in.<sup>2</sup>. The column was fitted with a pre-column pyrolysis unit

manufactured by Pye and the compounds investigated, after preliminary purification where necessary by column chromatography, were applied to the filament by dipping it into a solution of the pigment in a suitable solvent and drying it in a current of warm air. The temperature of pyrolysis was approximately 800°C and was maintained for 10 sec.

I thank Prof. L. Hörhammer for the samples of linarin and pectolinarin used in this work.

### 3·1-S Protein Fragment released from Reduced Wool by Trypsin

As one approach to the elucidation of the molecular arrangement in wool keratin, we have been using proteolytic enzymes under mild conditions to try to extract large molecules or aggregates of molecules from wool, which still preserve the configuration they had in the native fibre. In a previous communication<sup>1</sup> we described experiments designed to discover the cause of wool's resistance to proteolytic enzymes. An important reason may be the highly cross-linked structure which only allows the fibre to swell a small amount in aqueous solutions, so that the large enzyme molecules cannot easily diffuse into the fibre.

It was necessary, therefore, to find a treatment which would break disulphide bonds to allow the fibre to swell and the enzyme molecules to penetrate. At the same time, the treatment should preserve so far as possible the native arrangement of the molecules in the fibre. Elsewhere<sup>2</sup> we shall describe X-ray diffraction and deuterium exchange examination of keratin fibres which have been reduced with thioglycolic acid under various conditions. These experiments showed that it was possible to choose a reducing treatment (0·1 M thioglycolic acid, 0·1 M Na<sub>2</sub>HPO<sub>4</sub>, pH adjusted to 9·75, 18 h, 20° C) which did not irreversibly denature the fibre and yet permitted extensive (up to 50 per cent) digestion of reduced and rinsed Merino wool in 0·1 M Na<sub>2</sub>HPO<sub>4</sub> solution at pH 8·0, trypsin : substrate ratio 1 : 50, in 50 min at 20° C.

A further observation was that reduced fibres which had been re-oxidized by suspending them in a buffer at pH 7·0 and bubbling air through for several hours were no longer attacked by trypsin. If, therefore, trypsin did release large protein molecules or aggregates from reduced wool which were still in the native structure, then re-oxidation of these fragments in solution should prevent them from being broken down further by the enzyme. So for 2 h at 20° C air was bubbled through 0·1 M Na<sub>2</sub>HPO<sub>4</sub> solutions adjusted to pH 8·0 outside a dialysis bag containing the supernatant from centrifugation (1,250g for 5 min) of the reduced wool-enzyme reaction mixture. Dialysis was allowed to continue a further 18 h at 4° C without air bubbling before carrying out a run at 42,040 r.p.m. in the Spinco model E ultracentrifuge using a double sector synthetic boundary cell (Fig. 1). The asymmetry of the peak may mean that the keratin fragments released from the fibres were slowly broken down by the enzyme. If re-oxidation does prevent further attack on fragments in the native structure but does not prevent attack on denatured fragments, then it may prove possible to purify the native fragments by allowing the enzyme reaction to continue in the dialysis bag at 20° C after re-oxidation of the disulphide bonds.

An analytical ultracentrifuge run at 59,780 r.p.m. confirmed that, in fact, trypsin releases a large fragment from reduced Merino wool. The sedimentation coefficient of a 0·3 per cent solution in 0·1 M Na<sub>2</sub>HPO<sub>4</sub> solution at pH 8·0 was  $S_{20, \text{buffer}} \times 10^{13} = 3·1$ . This may be compared with light meromyosin<sup>3</sup>, molecular weight 100,000

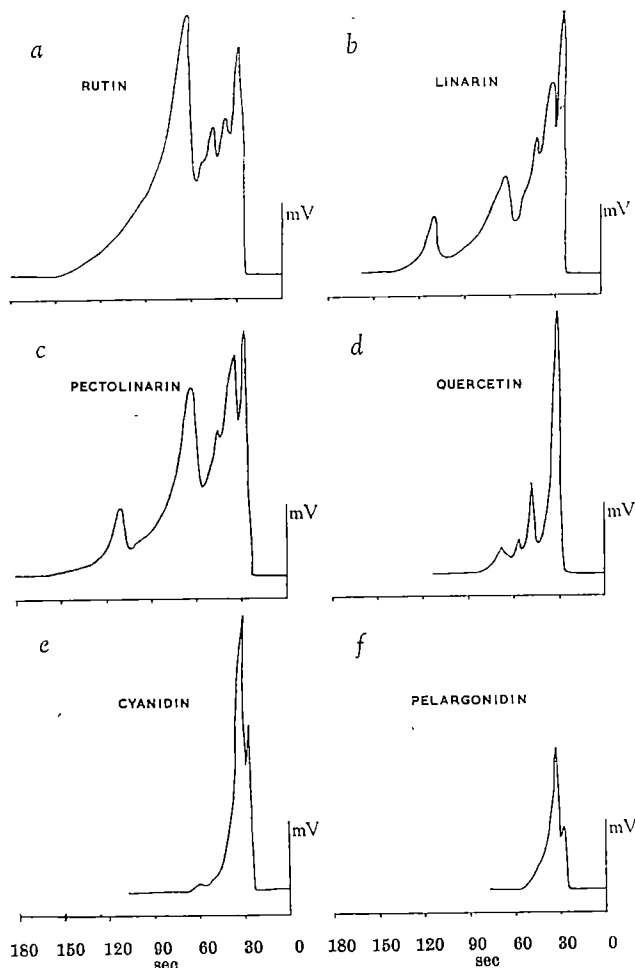

Fig. 1

The results obtained were found to be completely reproducible and the analyses were completed in a very short time; the pyrolytic products have not so far been identified. The flavonoid glycosides rutin (Fig. 1 (a)), linarin (Fig. 1 (b)) and pectolinarin (Fig. 1 (c)) were found to yield four characteristic peaks in each case; the flavonoid aglycone quercetin (Fig. 1 (d)) gave two major peaks only and the anthocyanin aglycones cyanidin (Fig. 1 (e)) and pelargonidin (Fig. 1 (f)) similarly gave two peaks; the peaks obtained from the two latter compounds were much closer together than those from quercetin. The retention times ( $R_t$ ) of the peaks obtained from the compounds investigated are shown in Table 1. It has thus been found that it is possible rapidly to assign a compound to its respective class, but this method has not so far afforded a means of identifying the pigment.

Table 1

$R_t$  of peaks obtained (sec)

Rutin	30	38	48	65	
Linarin	27	34	45	65	110
Pectolinarin	27	35	46	62	110
Quercetin	30	42	52*	62*	
Cyanidin	28	32			
Pelargonidin	28	32			

\* Minor peaks.

Fig. 1. Schlieren pattern from an ultracentrifuge run of a 1 per cent solution of protein released by trypsin from reduced wool. Buffer: 0.1 M  $\text{Na}_2\text{HPO}_4$ , adjusted to pH 8.0. Double sector synthetic boundary cell, bar angle  $75^\circ$ ,  $20^\circ\text{C}$ , 20 min after reaching 42,040 r.p.m.

$S_{20} \times 10^{13} = 2.8$ , or the  $\alpha$ -component from denatured tropocollagen<sup>4</sup>, molecular weight 100,000,  $S_{20,w} \times 10^{13} = 3.2$ . Purification and characterization of this high molecular weight constituent of wool keratin are proceeding.

## PHYSIOLOGY

### Anæsthesia and Receptive Fields

Hubel and Wiesel<sup>1,2</sup> have described the responses of cells in the cat's visual cortex to precise stimulation of the retina. They say: "A comparison of visual responses in the anaesthetized animal with those in the unanaesthetized unrestrained preparation<sup>1</sup> shows that the main differences lie in the frequency and firing patterns of maintained activity and in the vigour of responses, rather than in basic receptive field organization." They found that responses declined in vigour with anaesthesia.

A comparison we have recently made of receptive fields of cells in the cat's visual cortex in the unanaesthetized *cervæu isolé*<sup>3,4</sup> with those in the anaesthetized preparation has shown dramatic differences. Recordings were made in the way described by Burns, Heron and Pritchard<sup>4</sup>. Two sorts of unit have been examined: those the presence of which could only be detected by responses to stimuli and those that were spontaneously active. Six of the first type have been seen. These showed no spontaneous activity before, during or after anaesthesia with 'Pentothal' (the anaesthetic used by Hubel and Wiesel) in doses of 2–8 mg/kg. They did not respond to stimuli before anaesthesia<sup>4</sup>, but did so within a few minutes of the administration of 'Pentothal'. Their responses to black bars moving in a specific direction on a white background had disappeared between 30 and 60 min after giving the anaesthetic. In 12 spontaneously active cells receptive fields could be plotted before, during and after administration of 'Pentothal'. Receptive fields changed considerably under anaesthesia, but reverted, usually completely, to their original form within 1 h.

For example, a unit with a receptive field  $5^\circ$  from the area centralis of the contralateral retina, and about  $5^\circ$  wide, initially only responded to fast horizontal movement of a vertical black bar from left to right on a white background. After the preparation had been given 5 mg/kg 'Pentothal' the unit responded to fast and slow move-

ments of the black bar from left to right and from right to left. The unit also responded to vertical movement of the horizontally orientated bar in an area outside, but contiguous with, its original receptive field and  $5^\circ$  by  $8^\circ$  in size. Thirty-five min after giving the anaesthetic the unit only responded to left-to-right movements in its original receptive field.

All the units recorded in the primary visual areas of four cats have shown similar differences. The changes observed have always been, at least partially and usually completely, reversible. In contrast to Hubel and Wiesel's findings, units in the visual cortex seemed easier to stimulate during anaesthesia and more responsive to stimuli identical with those used before the anaesthesia. Our impression was that anaesthesia in some way made peripheral stimuli more significant and easier to detect, perhaps by reducing or cutting off many of the other inputs to a cortical cell. It is interesting that whereas Burns, Heron and Pritchard<sup>4</sup> found that units not spontaneously active never responded to stimuli, many of the responses recorded by Hubel and Wiesel were from otherwise inactive units. This must reflect a difference between the unanaesthetized and anaesthetized preparations, as giving anaesthetic in our experiments revealed many hitherto unresponsive units.

It is also interesting that we have observed persistent changes in the frequency and distribution of maintained activity of cortical units during different levels of retinal illumination. Both Burns, Heron and Pritchard, and Hubel and Wiesel, saw responses only at the times of changes of illumination. Stimulation also caused changes in slope of both parts of the interval histogram described by Smith and Smith<sup>5</sup>.

Two of the possible explanations for the discrepancies between our results and those of Hubel and Wiesel are: (1) intact brain and *cervæu isolé* are not directly comparable; (2) Hubel and Wiesel never observed the same cell before and during anaesthesia, whereas all cells examined here were recorded in both states.

### Mesencephalic Reticular Activating System and Cortical Acetylcholine Output

THERE is a great deal of indirect evidence<sup>1,2</sup> for the participation of cholinergic pathways in the electroencephalographic (EEG) arousal response. Parasympathomimetic agents, including acetylcholine (ACh) and cholinesterase inhibitors, cause EEG desynchronization similar to the EEG changes accompanying behavioural arousal or the stimulation of the mesencephalic reticular formation. Furthermore, atropine blocks EEG desynchronization produced by the above methods. Mitchell<sup>3</sup> has reported that stimulation of specific afferent pathways leading to the somatosensory cortex caused an increased release of ACh from this area. Using similar techniques we investigated the effect of mesencephalic reticular formation stimulation on cortical ACh output.

Cats weighing 2.5–3.5 kg were anaesthetized throughout the experiments with 1–1.5 per cent halothane administered by means of a respiratory pump. A bipolar electrode was placed stereotactically into the mesencephalic tegmentum (co-ordinates: A, 3.0; L, 4.0; H, -1.0) and this area was stimulated every 10 sec with trains of pulses of 8–12 V and of 0.1 m/sec duration for 1 sec at

Fig. 1. Letters above EEG tracings indicate time of recording in relation to ACh output as shown in graph. During periods marked by thick line, stimulation of the reticular formation. At arrow, 1 mg/kg atropine sulphate injected i.v. EEG calibration: 0.1 mV, 1 sec

a rate of 100/sec. ACh was collected from the ipsilateral cortex in 0.25 ml. Locke's solution contained in 'Perspex' cylinders covering 0.75 cm<sup>2</sup> of the cortex. Collection of ACh was started after exposing the cortex for 30 min to 0.25 mg/ml. phospholine iodide. The Locke's solution placed on the cortex in which ACh release was estimated contained 1 µg/ml. eserine salicylate and the same concentration of atropine sulphate, a procedure shown previously<sup>4</sup> to enhance ACh output. The released ACh was assayed on dorsal strips of leech-muscle suspended in a microbath<sup>5</sup>. The EEG was recorded by means of small non-polarizing wick electrodes on a Grass electroencephalograph.

As shown in Fig. 1, in the absence of any stimulation of the reticular formation the EEG showed large, slow-wave sleep pattern, although the lead on the area exposed to the cholinesterase inhibitor frequently showed an activity of higher frequency. Stimulation of the reticular formation caused a continuous activation of the EEG during the 10–15 min collection period. In the same time ACh output from the cortex increased 5–6 times with large amounts of ACh still appearing in the period following the stimulation. Injection of 1 mg/kg atropine sulphate intravenously made the high voltage, slow-wave pattern more pronounced and practically abolished the EEG desynchronization resulting from the stimulation of the reticular formation. However, this dose of atropine did not prevent the increase in ACh output due to reticular formation stimulation.

In different experiments two cylinders were placed on the cortex, one on the posteroculic cortex, on the area of maximum evoked potentials resulting from the stimulation of the contralateral forepaw and a second, farther back, on the medial ectosylvian gyrus. Following the inhibition of cholinesterase in both areas, ACh output was measured concurrently. As shown in Fig. 2A, stimulation of the contralateral forepaw increased ACh output mostly from the somatosensory cortex, but there was a considerable increase in ACh output from the parietal cortex also,

Fig. 2. A, 1 per cent, B, 1.5 per cent halothane anaesthesia. Solid line ACh output from posteroculic gyrus; broken line from medial ectosylvian gyrus; a, 1/sec stimulation of contralateral forepaw; b, stimulation of ipsilateral reticular formation

due probably to the activation of the reticular formation through the collaterals of the specific afferent pathways. When the anaesthesia was deepened (Fig. 2B) peripheral stimulation augmented ACh output only from the sensory cortex, although to a much lesser extent than under lighter anaesthesia. Stimulation of the tegmental reticular formation increased ACh output to about the same degree from both cortical areas.

These observations show unequivocally the participation of cholinergic neurones in the EEG arousal response. The finding that atropine blocked the EEG signs of arousal without affecting the increase in ACh output indicates that the enhanced output of ACh was not the result of a general increase in neuronal activity in the underlying cortex during EEG arousal. The simplest interpretation of the action of atropine on EEG therefore is that it blocks the postsynaptic effect of ACh in the cortex where, as has been shown by Krnjević and Phillis<sup>6</sup>, it also antagonizes the stimulating effect of electrophoretically applied ACh. The present observations also demonstrate that cholinergic pathways are part of at least two distinct cortical systems. One is the specific corticopetal system producing increased ACh release in the sensory area, as had been shown before by Mitchell<sup>3</sup>, and a non-specific system involved in the EEG arousal response, producing increased ACh release in a wide area of the cortex. This widespread cholinergic system has been demonstrated histochemically by Shute and Lewis<sup>7</sup>, who found important cholinergic tracts ascending from the mid-brain tegmentum to the cortex and to other parts of the fore-brain.

### Effect of Tissue Size on Measurements of Sodium, Potassium and Water Contents of Isolated Rat Ventricular Tissue

DURING the course of experiments designed to examine the effects of inhalation anaesthetics on the sodium, potassium and water contents of isolated rat atrial tissue<sup>1</sup>, it was noted that the standard deviations of the sodium values were rather high. These values were thought to be unreliable and were therefore not reported. It was felt that part of the deviations in sodium values could be explained by the fact that uniform blotting procedures were not used on all tissues, thus removing variable quantities of sodium-rich bathing medium. Part of the difference could also be explained on the basis of contamination of the tissue or its digest from any number of sources, despite diligent care to use demineralized water and clean apparatus. Since the tissue was so small (about 50 mg) and its sodium content so small, it is easy to see that the slightest contamination would give erroneous results. As the experiments progressed, however, and greater attention was directed to the possibilities of contamination, the sodium values decreased and the standard deviations also decreased.

Since contamination did appear to play a part, it seemed desirable to use larger pieces of tissue so that the effects

of contamination would be minimal. The isolated rat ventricle was thus used. In order to assess the effects of tissue size on sodium values, small pieces cut from the right and left ventricle were compared with the intact ventricle which was split open before blotting.

Freshly dissected tissues were used in all cases. The hearts from rats killed by decapitation were placed in Krebs-Henseleit bicarbonate solution (modified to contain 1/2 the normal calcium concentration and 1 g glucose/l.). The auricles were removed and discarded. The ventricle was split in half and, when appropriate, small pieces of tissue from the right and left ventricle were removed. All tissues were blotted 20 times<sup>2</sup> on Whatman No. 44 filter paper, a fresh piece of filter paper being used after each 5 blottings. The tissues were then dried at 95° C for at least 24 h. The small pieces of tissue were then digested in 0.5 ml. concentrated HNO<sub>3</sub> in a plastic vial or bottle for at least 24 h. The volume was then brought to 25 ml. with demineralized water, and analyses for sodium and potassium were made with an Evans Electro-selenium, Ltd., flame photometer. The intact ventricles, which weighed about 10 times more than the small pieces, were digested in 5 ml. concentrated HNO<sub>3</sub> and diluted to 250 ml. with demineralized water before analysis. The results are given in Table 1.

Table 1. EFFECT OF TISSUE SIZE ON WATER, SODIUM AND POTASSIUM CONTENTS OF FRESHLY DISSECTED RAT VENTRICULAR TISSUE

	Sections of right ventricle (5)*	Sections of left ventricle (5)	Intact ventricles (10)
Mean wet weight (mg)	36.6	72.0	502.3
Per cent H <sub>2</sub> O	77.0 ± 0.65†	76.1 ± 1.23	76.9 ± 0.53
M.equiv. Na <sup>+</sup> /kg wet tissue	94.5 ± 13.0	74.8 ± 6.2	46.8 ± 3.8
M.equiv. Na <sup>+</sup> /kg dry tissue	412 ± 58	314 ± 28	203 ± 19
M.equiv. K <sup>+</sup> /kg wet tissue	71 ± 9	73.3 ± 5.6	83.5 ± 4.7
M.equiv. K <sup>+</sup> /kg dry tissue	309 ± 42	308 ± 18	360 ± 20
Na <sup>+</sup> /K <sup>+</sup>	1.33	1.02	0.56

\* Number of tissues.

† Standard deviation.

Several facts are evident from Table 1. (1) Sodium content decreased as tissue size increased and standard deviation of sodium values also decreased as tissue size increased. (2) Percentage water was not measurably altered by tissue size. (3) Potassium content was not altered as much as sodium content by tissue size, although the large intact ventricles showed higher potassium values than either of the 2 smaller pieces of tissue. This may be due to leakage of potassium from the cut surfaces of the smaller tissues, which surface is larger relative to the mass than is the case with the intact ventricle preparation. (4) The Na<sup>+</sup>/K<sup>+</sup> ratio was markedly reduced as the tissue size increased.

It is evident that the larger the tissue size (or the smaller its surface area in relation to its mass) the less the tissue content of sodium is affected by contamination or by the medium in which the tissues were dissected. Thus, sodium values from large tissues would more nearly reflect true sodium content of the tissue. Since the potassium values are higher for the larger tissues, they also probably more nearly reflect true tissue potassium content. For these reasons the intact ventricle preparation is to be preferred over small pieces of ventricular tissue for investigations involving tissue sodium and potassium determinations.

This investigation was supported in part by research grant HE-07718 and in part with facilities provided by the Heart Research Center grant H-6308 from the National Heart Institute, U.S. Public Health Service.

### Effect of Indolyl-3-acetic Acid on the Permeability of Membranes in Storage Tissue

A STRIKING difference between the response of coleoptile tissue and storage tissue to applied auxin is that the former is immediate and the latter exhibits a lag period<sup>1-3</sup>. Sperling and Laties<sup>4</sup> have recently shown that in potato or Jerusalem artichoke tissue slices auxin response depends on the progress of metabolic changes associated with the lag period (ageing of tissue), and auxin had to be applied to fresh tissue to be effective. A similar characteristic feature of freshly cut storage tissue is that it requires the completion of a lag period before salt is accumulated. At least in the case of potassium this phenomenon was shown to be due to a reduction in the permeability of the outer cell membrane<sup>5</sup>.

Efforts to establish a coherent relationship between molecular auxin action and the induced cellular expansion have been inconclusive. Recently, doubts have been cast on promising hypotheses which involve plasticization of cell walls, dependent on auxin-induced methylation of galacturonic acids<sup>6</sup> or on the removal of calcium bridges from the wall (chelation theory)<sup>7,8</sup>. The observations presented here indicate that the primary site of auxin action may be revealed by examining its effect on the cell membrane.

Disks of beetroot tissue (15 mm diameter, 1 mm thick, average weight approximately 180 mg, var. 'Crimson Globe') were washed rapidly in three rinses of distilled water to remove cell debris before commencing the experimental treatment. Normally, fresh tissue was used but, when required, tissue was aged by placing the disks in vigorously aerated distilled water for 7 days, changing the aeration medium daily. Disks were incubated at 23°–24° C in batches of 25–75 per 150–500 ml. of aerated solutions to be tested. Each treatment was performed in triplicate. Potassium and calcium contents of the external solutions were determined by flame photometry.

Fig. 1 shows typical curves for the potassium concentration of the external solution when disks of beetroot were incubated in distilled water, in 0.1 p.p.m. or in 10 p.p.m. indolyl-3-acetic acid (IAA). After 15 h in distilled water, net movement of potassium ions was usually negligible, since potassium influx and efflux balanced each other<sup>9</sup> and a marked change at approximately 30–40 h from the start of the experiment due to a lowering of the efflux indicated the completion of the lag phase<sup>9</sup>. The IAA-induced changes in the potassium concentration of the external solution show that IAA did not change the duration of the lag period for salt uptake, although it increased the net leakage of potassium to the external solution. Rates of uptake and leakage in m.equiv./kg fresh weight/h (uptake shown +, leakage –) were + 0.008 ± 0.017, – 0.088 ± 0.013 and – 0.089 ± 0.006 for distilled water, 0.1 p.p.m. IAA and 10 p.p.m. IAA, respectively, during the period from 15 to 40 h, and + 0.171 ± 0.015, + 0.180 ± 0.017 and + 0.177 ± 0.025, respectively, during the period from 40 to 64 h. Thus, once the lag phase was completed rates of uptake remained unaltered by the auxin treatment.

Results presented in Table 1 show that IAA over a wide range of concentrations induced an increased leakage in fresh tissue only; it did not affect the amount of potassium associated with the apparent free space (A.F.S.). In aged tissue influx is much larger than efflux and therefore leakage of potassium can only be demonstrated with the help of tracers or by maintaining the potassium concentrations in the external solutions at less than 10<sup>-5</sup> M. Hence, the figures for leakage in aged tissue depend on experimental conditions but serve to indicate that IAA is effective only at a very high concentration (100 p.p.m.) in increasing the permeability of the cell membrane system: ageing appeared to reduce the sensitivity of the tissue towards applied auxin. Root tissues are very

Fig. 1. Potassium contents of the external solution (mM/l.) due to uptake or release of ions by fresh cut beetroot tissue (14.0 g/500 ml.) against time (h). O, Distilled water; Δ, IAA 0.1 p.p.m.; ◻, IAA 10 p.p.m.

sensitive to auxin and their elongation is inhibited by concentrations as low as 10<sup>-11</sup> M (1.75 × 10<sup>-6</sup> p.p.m.)<sup>10</sup>, unless the tissue is depleted of auxin beforehand<sup>11</sup>. Generally, stem and coleoptile tissue seem to respond to concentrations of the order of 10<sup>6</sup> higher than those for root tissues. Therefore the decreased sensitivity of storage tissue on ageing may represent a change equivalent to a hypothetical transformation of root tissue into tissue with stem properties. According to Sperling and Laties<sup>4</sup>, the effectiveness of auxin depends on the changes in metabolism during the process of ageing. While this may be true, I suggest that the primary action of auxin is to bring about an immediate change in membrane permeability while the tissue is receptive. Jenkinson and Scott's<sup>12</sup> hypothesis of a feedback mechanism for the oscillations in bioelectric potentials observed in bean roots is based on a similar assumption.

Ethylenediamine tetraacetic acid (EDTA) is known to promote cellular expansion in certain tissues<sup>7</sup>. Like IAA it caused an increase in leakage when applied to storage tissue (Table 2); this leakage was strictly depend-

Table 1. The effect of IAA on the amount of potassium associated with the apparent free space (A.F.S.) and on leakage of potassium (m.equiv./kg fresh weight) in fresh and aged beetroot tissue, measured at intervals of 0.5, 1, 2, 4 or 8 h (1.8 g tissue/20 ml. solution; 10 ml. solution removed at each sampling and replaced by distilled water or appropriate IAA solution)

Treatment	A.F.S.	Fresh tissue Total leakage over:		A.F.S.	Aged tissue Total leakage over:	
		0–0.5 h	0.5–8 h		0–0.5 h	0.5–8 h

Table 2. The effect of IAA or EDTA on rates of net potassium uptake (+) or leakage (-) in m.equiv./kg h before (8-30 h) and after completion of the lag phase (30-54 h) in beetroot tissue (4.4 g/150 ml. solution)

Treatment	8-30 h	30-54 h
H <sub>2</sub> O	-0.088 ± 0.002*	+0.205 ± 0.018*
5 × 10 <sup>-5</sup> M IAA	-0.335 ± 0.013	+0.195 ± 0.016
5 × 10 <sup>-5</sup> M EDTA	-0.167 ± 0.010	+0.185 ± 0.028

\* Standard errors of mean determinations.

Table 3. The amount of calcium removed from beetroot tissue by solutions of IAA or EDTA at various intervals after incubation (cumulative values), expressed as mg/kg fresh weight of tissue (calcium present in tissue at time of incubation 148 ± 30 mg/kg fr. wt.)

Treatment	2	Interval after incubation (h)				90
		8	30	54		
H <sub>2</sub> O	4.1	8.1	23.6	27.6	14.0	
5 × 10 <sup>-5</sup> M IAA	4.0	8.7	24.8	28.3	15.0	
5 × 10 <sup>-5</sup> M EDTA	91.0	93.0	93.0	87.0	78.0	

ent on the molar ratio of EDTA in solution to calcium present in the tissue. In contrast with the IAA-induced leakage, the effect of  $0.5 \times 10^{-5}$  M EDTA could easily be reversed by addition of an equivalent amount of calcium. Table 3 shows the amounts of calcium in solution, and thus removed from tissue by  $0.5 \times 10^{-5}$  M EDTA and  $0.5 \times 10^{-5}$  M (8.75 p.p.m.) IAA respectively. It is obvious that leakages induced by EDTA and by IAA respectively are based on different principles. It should be rewarding to obtain more detailed knowledge of the mechanism by which IAA causes the immediate increase of membrane permeability.

## Effect of Cardiac Glycosides on Neuromuscular Transmission

BIRKS has recently suggested that raised intracellular sodium concentrations increase transmitter release from pre-synaptic nerve terminals<sup>1</sup>. This hypothesis is based on measurements of the amount of acetylcholine which was released from the perfused cat superior cervical ganglion and from cholinergic nerve terminals in frog sartorii when active sodium transport had been inhibited with the cardiac glycosides digoxin or ouabain. In the neuromuscular preparation an increased acetylcholine release was signalled by increases both in the quantal content of the endplate potentials (e.p.p.s) and in the frequency of spontaneous miniature endplate potentials (m.e.p.p.s.). These drugs have been tested at a mammalian neuromuscular junction in the present investigation in an attempt to demonstrate the phenomena at this synapse.

The rat phrenic nerve-diaphragm preparation, the bathing solution and the intracellular recording technique have been previously described<sup>2</sup>. Neuromuscular transmission was blocked by raising the magnesium chloride concentration of the bathing solution to 11-14 mM and the temperature was maintained at 33°-37° C. Intracellular e.p.p.s and m.e.p.p.s were recorded from the endplate region of muscle cells with glass microelectrodes filled with 3 M potassium chloride. The phrenic nerve, immersed in paraffin, was stimulated at 1- or 2-sec intervals through a pair of platinum electrodes and the sweep speed of the oscilloscope adjusted to allow simultaneous

recording of the elicited e.p.p.s and of the m.e.p.p.s. A faster oscilloscope sweep speed was used for recording the time course of e.p.p.s. The oscilloscope traces were recorded on moving film, which was later read using a photographic enlarger. Ouabain ('Strophanthin-G', British Drug Houses) was weighed dry and dissolved in control solutions to give concentrations of 1.0 to  $1.37 \times 10^{-5}$  M. 'Digoxin' (Burroughs Wellcome), supplied dissolved in ethyl alcohol, was added to control solutions so that the final concentration of digoxin was  $7.7 \times 10^{-6}$  M to  $1.3 \times 10^{-5}$  M and of ethyl alcohol 0.1-1.0 per cent v/v.

Fig. 1A shows that the amplitude of both e.p.p.s and m.e.p.p.s increases in ouabain ( $1.37 \times 10^{-5}$  M). The average e.p.p. and m.e.p.p. amplitudes are illustrated in the sequence: in control solution, after 32 and 60 min in the ouabain solution, and after 20 min in control solution. On the right of each e.p.p. is shown a typical m.e.p.p. photographed at the same oscilloscope sweep speed, and above, samples of m.e.p.p.s at a slower sweep speed and greater amplification. For calculation of quantal content, the m.e.p.p.s were recorded at the higher amplification and an average of 60 observations was used as an estimate of the size of a single quantum.

The effect of ouabain on the amplitudes of both e.p.p.s and m.e.p.p.s is shown in Fig. 1B. The amplitudes of e.p.p.s (filled circles) and m.e.p.p.s (open squares) are plotted as a ratio of the control amplitude (horizontal broken line), each point representing an average amplitude derived from 60 observations. One of the striking features of the graph is the parallelism between changes in e.p.p. and m.e.p.p. amplitudes. After 20-30 min there was a progressive increase in size until at 60 min both the e.p.p. and m.e.p.p. amplitudes were 1.7 to 1.8 times the control. In spite of the increased amplitude of the e.p.p. in ouabain, there was no significant change in the quantal content (Fig. 1C) which was calculated from the ratio of average e.p.p. to average m.e.p.p. amplitude and plotted as a ratio of the quantal content in control solution (horizontal broken line Fig. 1C). M.e.p.p. frequency per second was also relatively constant (Fig. 1D), the small increase being within the range often observed over a similar time in control solution. After only 3 min in ouabain, the half decay time of the e.p.p.s showed an appreciable increase in duration from 0.30 msec to 0.41 msec and then lengthened progressively until after 60 min in ouabain it had more than doubled (Fig. 1E). Each point is an average of the half decay times of 6-10 e.p.p.s ranging in size from the largest to the smallest observed. After 20 min in control solution the half decay time showed very little recovery towards the original duration. The amplitude of the m.e.p.p.s continued to increase for 10-20 min after removal of the ouabain and then began to fall, but after 20 min in control solution the amplitudes were still greater than they had been in the ouabain.

Thus the m.e.p.p. amplitude 9 min after the ouabain had been washed out was three times the control size, but 11 min later had decreased to 2.2 times the control amplitude (Fig. 1B). In this experiment e.p.p. amplitudes were not recorded 9 min after removal of the ouabain, but in similar experiments there was usually a partial reversal of the potentiation, the degree of reversal varying with the time of exposure to ouabain. The quantal content of the e.p.p.s (Fig. 1C) and the m.e.p.p. frequency (Fig. 1D) remained relatively constant following removal of the ouabain. The muscle resting membrane potential was stable at  $68 \pm 3$  mV throughout the experiment. Results similar to those shown in Fig. 1 were observed in ouabain concentrations ranging from 1.0 to  $1.37 \times 10^{-5}$  M. These concentrations of ouabain would be expected to inhibit active sodium transport<sup>3,4</sup>, yet produced no increase in the quantal content of the e.p.p.s or in the m.e.p.p. frequency and, hence, it can be concluded that there was no increase in acetylcholine release. On the other hand, an increased sensitivity of the muscle membrane to acetylcholine was shown by the growth in size of the m.e.p.p.s (Fig. 1B).

Further evidence of post-synaptic action is revealed by the increased half decay time of the e.p.p.s (Fig. 1E). The nature of these post-synaptic effects has not been pursued in the work recorded here, but it is of interest to note that ouabain has been shown to increase the sensitivity of ganglion cells and cardiac muscle fibres<sup>4,5</sup> to acetylcholine and other depolarizing agents. It is generally agreed that this is not due to an anticholinesterase action<sup>5</sup>. The increase in the amplitude and the lengthened decay time of the e.p.p.s can both be accounted for by postulating that ouabain increased the electrical resistance of the muscle membrane. This postulate is in accord with the recent observations that ouabain lowers electrical conductance in frog skin<sup>6</sup>.

In contrast, digoxin, even in the lowest concentration used, caused an appreciable increase in e.p.p. amplitude, but there was not an equivalent increase in m.e.p.p. amplitude. The quantal content of e.p.p.s in  $7.7 \times 10^{-6}$  M digoxin plotted as a ratio of the control quantal content (broken horizontal line) is shown in Fig. 2C and an increase is apparent as early as 10 min in the digoxin. After 34 min in digoxin, the average quantal content of e.p.p.s had increased by 40–50 per cent. Full reversal of this potentiation was evident 60 min after the digoxin had been washed out. Alcohol alone, in the same concentration (0.24 per cent v/v) in which the digoxin was dissolved, caused a similar increase in the quantal content of e.p.p.s and the potentiation followed a similar time course (Fig. 2C). In other experiments ethyl alcohol (1 per cent v/v) caused a more marked increase in e.p.p. amplitude. Fig. 2B shows the change in e.p.p. size graphed as a ratio of the control

Fig. 1. Effect of ouabain ( $1.37 \times 10^{-5}$  M) on neuromuscular transmission. A, Illustrations of spontaneous miniature endplate potentials above, and intracellular endplate potentials below. Fig. 2. The effect of ethanol and digoxin on neuromuscular transmission. A, Illustrations of average endplate potentials in the solution sequence: control, ethanol (1 per cent), control digoxin. Vertical calibration: 1 mV. Time calibration: msec. B, Ordinate: ratio of average endplate potential amplitude to control, amplitude. The vertical broken lines denote solution changes in the same sequence as in A.  $\text{MgCl}_2$  11 mM,  $33^\circ\text{C}$ . C, Quantal content of average endplate potentials in 0.24 per cent ethanol v/v (open squares) and digoxin  $7.7 \times 10^{-6}$  M in 0.24 per cent ethanol (closed circles) as a ratio of the control quantal content against time.  $\text{MgCl}_2$  14 mM,  $35^\circ\text{C}$

amplitude (horizontal broken line). In Fig. 2A these changes in e.p.p. amplitude are illustrated. The average e.p.p. amplitude has increased 125 per cent within 19 min exposure to the alcohol (Fig. 1A and B). Full recovery to the amplitude in control solution was observed 15 min after washing out the alcohol. Digoxin  $1.3 \times 10^{-5}$  M in 1 per cent ethyl alcohol (v/v) was then substituted for the control solution, and after exposure for 12 min to the digoxin the e.p.p.s had again begun to increase in amplitude. After 17 min in digoxin, the e.p.p. amplitude had increased 95 per cent. In further experiments increases in the quantal contents of e.p.p.s have been observed in ethyl alcohol concentrations as low as 0.05 per cent v/v.

Although ouabain and digoxin are presumed to have a common action in inhibiting active sodium transport across membranes and allowing an intracellular accumulation of sodium ions<sup>3,7,8</sup>, their effects at the rat neuromuscular junction are dissimilar. It is clear that the foregoing ouabain concentrations increased the e.p.p. amplitude not by a greater release of acetylcholine but rather by changes in the muscle membrane which made it more sensitive to acetylcholine. In contrast, digoxin in alcohol caused an early (within 10 min) pre-synaptic increase in e.p.p. amplitude (Fig. 2). It is likely that this increased acetylcholine release in digoxin was not an effect of the digoxin itself, but was due to the ethyl alcohol present as solvent. These results thus do not support the hypothesis proposed by Birks.

## Afferent Discharges from Laryngeal Articular Mechanoreceptors

In previous communications<sup>1-3</sup> we have described the afferent nerve supply of the laryngeal joints, and the various types of articular nerve ending innervated thereby. We have also shown that electrical stimulation of the larger diameter fibres in the laryngeal articular nerves—which fibres terminate in corpuscular end organs in the capsules of the laryngeal joints<sup>2,3</sup>—gives rise to reflexly co-ordinated contraction and relaxation of the laryngeal muscles which can be detected visually and electromyographically<sup>4,5</sup>. We have further shown that similar reflexly co-ordinated changes in the tone of the laryngeal muscles are provoked by specific passive movements of isolated laryngeal joints<sup>4,5</sup>. We now wish to report that oscillographic analysis of the impulse traffic in the articular nerves innervating the cricothyroid joint from the recurrent laryngeal nerve, and in the recurrent nerve itself, has identified the mechanoreceptor afferent discharges responsible for the reflex muscular responses to passive movement of the joint.

For this purpose, the left cricothyroid joint was isolated from the lamina of the thyroid cartilage, and from the attachments of the cricothyroid and inferior constrictor muscles, in six cats lightly anaesthetized with pentobarbitone. The left thyroid lamina was then removed, to expose the intrinsic muscles and nerves of the larynx. Non-elastic threads were tied through the residual articulated fragment of the inferior cornu of the thyroid cartilage, and graduated passive movements of the cricothyroid joint were performed by attaching small weights to these threads, over pulley surfaces. Movements were performed in four planes mutually at right angles (that is, in cranial, caudal, anteromedial and anterolateral directions), as in previous experiments<sup>4,5</sup>. All responses were tested at various phases of the spontaneous respiratory cycle.

Bipolar, chlorided silver recording electrodes were placed in contact with one or more of the articular nerves supplying the joint, and with the trunk of the ipsilateral recurrent laryngeal nerve proximal and distal to the origin of its articular branches. Impulses from each recording site were fed in turn through a Grass pre-amplifier to the upper beam of a Tektronix oscilloscope, the lower beam being used for calibration and timing signals. Activity was photographed on film with an electrically controlled camera, triggered synchronously with the sweep mechanism of the oscilloscope.

Recordings were first made of the resting activity in the recurrent laryngeal nerve and in its articular branches in the absence of joint traction. The responses in the articular nerves and in the recurrent laryngeal nerve to displacement of the cricothyroid joint in four directions were then examined, with concurrent observation of the laryngeal muscular responses provoked thereby. The procedure was then repeated after bilateral section of the superior laryngeal nerves proximal to the origin of their external branches; after section of the ipsilateral recurrent laryngeal nerve distal to the origin of its articular branches; after section of the recurrent laryngeal nerve in the neck, proximal to the recording electrodes; and after section of the articular nerves distal to the recording electrodes. The effects of local anaesthesia of the joint capsule (with 2 per cent 'Lignocaine' hydrochloride solution), and of electrocoagulation of the joint capsule, were also examined.

In all experiments, the nerves and other exposed tissues were submerged in a pool of warm mineral oil. The animals were kept warm on a thermostatically regulated, heated operating table. Operative procedures were performed with microsurgical instruments and a Zeiss operating microscope.

Movements of the cricothyroid joint—but in caudal and anteromedial directions only—produced very brief bursts of rapidly adapting, high-amplitude potentials in

the articular nerves at the onset of movement, which passed proximally into the ipsilateral recurrent laryngeal nerve. No such responses were provoked by movements in other directions. No slowly adapting discharges were seen in the articular nerves during movement or sustained joint displacement; but release of the displaced joint gave rise to a second brief burst of rapidly adapting potentials in the articular nerves at the moment of release. These responses in the articular nerves were reversibly abolished (for about 40–60 min) by local anaesthetic infiltration of the joint capsule. They were irreversibly abolished by electrocoagulation of the joint capsule, and by section of the articular nerves distal (but not proximal) to the recording electrodes.

In the recurrent laryngeal nerve, the fast potential transients produced by joint movement were followed—after a short interval—by a more prolonged episode of irregular asynchronous potentials which was accompanied by a twitch of the adductor muscles of the larynx. This delayed asynchronous discharge (and the muscle twitch)—but not the initial rapidly adapting response—was irreversibly abolished by section of the recurrent laryngeal nerve proximal to the recording electrodes; and the same effect (but reversible) was produced by increasing general anaesthesia.

Bilateral section of the superior laryngeal nerves had no effect on the responses in the recurrent laryngeal nerve. Both the rapidly adapting and the delayed asynchronous discharges in this nerve (as well as the muscle twitch) were reversibly abolished by local anaesthesia of the joint capsule, and irreversibly abolished by electrocoagulation of the joint capsule and by section of the articular nerves. The muscle twitch, but not the rapidly adapting or delayed asynchronous discharges in the recurrent laryngeal nerve, was abolished by section of the recurrent nerve distal to the origin of its articular branches.

These experiments confirm that passive movements of the isolated cricothyroid joint in appropriate directions provoke reflex changes in the tone of the laryngeal muscles by impulses discharged into the ipsilateral recurrent laryngeal nerve through its articular branches<sup>4,5</sup>. They indicate that, after a brief central delay, these afferent impulses reflexly excite motoneurons in the brain stem from which efferent impulses are projected to intrinsic muscles of the larynx through motor fibres in the recurrent laryngeal nerve. They further indicate that the articular receptors responsible for the initiation of these reflex effects are rapidly adapting mechanoreceptors located in the capsule of the cricothyroid joint. Appropriate end-organs (Type II corpuscles) have been identified previously in the fibrous capsule of this and the other laryngeal joints<sup>1-3</sup>, and shown (in the case of the cricothyroid joint) to be innervated by large myelinated fibres in the articular branches of the ipsilateral recurrent laryngeal nerve<sup>3</sup>. The lack of slowly adapting mechanoreceptor discharges from the cricothyroid joint is explained by the absence of the appropriate category of end-organs (Type I corpuscles) from its capsule<sup>2</sup>—although a few such are present in the capsule of the crico-arytenoid joint<sup>3</sup>. The observations reported here indicate that the initial fast transient fired into the recurrent laryngeal nerve through its articular branches represents the response of Type II mechanoreceptors in the capsule of the cricothyroid joint to the stresses produced by movement of the joint; and that the delayed asynchronous discharge in the recurrent nerve represents the (polysynaptic) reflex response thereto in motor fibres innervating the intrinsic laryngeal muscles that provokes their changes in tone when the joint is moved<sup>4,5</sup>.

These findings provide further confirmation of the operation of articular mechanoreceptor reflexes in the larynx<sup>1,3-5</sup> contributing to the co-ordinated adjustment of the tone of its intrinsic muscles. They show that these reflex mechanisms are triggered primarily by very sensitive, rapidly adapting receptors in the laryngeal joint

capsules, from which impulses travel centripetally at high velocity in large myelinated afferent fibres in the laryngeal nerves. In addition, they support the view<sup>1,2,4</sup> that the principal innervation of the cricothyroid joint is by way of articular branches of the ipsilateral recurrent laryngeal nerve, and that the directions of movement of this joint that are critical for excitation of its capsular mechanoreceptors are those involving caudal and antero-medial displacements<sup>4,5</sup>.

## Mechanism of Sugar Transport in Brain Slices

LITTLE work has been reported on the mechanism by which sugar is transported into brain cells. The results of the brain-perfusion experiments of Geiger *et al.*<sup>1</sup> suggest that a carrier-mediated transport process may be involved; but there are few quantitative data to support this possibility. This communication concerns the results of investigations of the transport of D-xylose into the cells of brain slices incubated *in vitro*.

Guinea-pig brain slices composed mainly of cerebral cortex were incubated for 30 min at 37° C in a bicarbonate medium similar to that recommended by Krebs and Henseleit<sup>2</sup>. The medium contained 12 mM sodium pyruvate to act as nutrient and 10 mM raffinose (see following), and was gassed with a mixture of 95 per cent oxygen/5 per cent carbon dioxide. Experiments showed that at the start of this incubation period the potassium content of the brain slice fell sharply while the sodium content increased. After some 20 min, however, potassium was re-accumulated and sodium extruded by the slices, so that by the end of the 30 min period the intracellular concentrations of these ions had stabilized at levels not differing greatly from those reported to occur *in vivo*<sup>3</sup>. The slices were then drained and quickly transferred to a second medium which was similar to the first, but contained, in addition, xylose or xylose and glucose or xylose and 2-deoxyglucose.

After a short period (usually less than 10 min because of the speed of the sugar-transport process) the slices were rapidly separated from the medium and analysed as follows. The total water content was determined from the wet and dry weights of slice samples. The xylose and raffinose contents of the tissues were estimated in protein-free solutions by the methods of Roe and Rice<sup>4</sup> and Cole<sup>5</sup>, respectively. The mean concentrations of xylose and raffinose in the tissue were expressed in terms of the spaces<sup>6</sup> occupied by these solutes. The tissue xylose was then partitioned between the apparent intra-

cellular (*Ic*) and extracellular (*Ec*) compartments, on the assumption that raffinose was entirely extracellular in distribution, as shown:

$$\text{Intracellular xylose concentration} = \frac{(\text{xylose space} - \text{raffinose space})}{(\text{total water} - \text{raffinose space})} \text{medium xylose concentration}$$

$$\text{Fractional penetration (f)} = \frac{Ic \text{ xylose concentration}}{\text{Medium xylose concentration}}$$

Values for the intracellular xylose concentrations expressed as fractions of the medium concentrations are given in Table 1 for a series of medium concentrations.

Increases in the intracellular xylose concentration failed to keep pace with increases in the medium concentration so that the fractional penetration of brain cells by xylose diminished as the medium concentration increased. If xylose were transported predominantly by a diffusion mechanism, the fractional penetration would be independent of the concentration of xylose in the medium. The results are rather what one would expect on the basis of a process which can be saturated such as carrier-mediated transport. The results further show that when the medium contains a low concentration of xylose the fractional penetration can exceed unity. This suggests that xylose can be accumulated in the cells of the preparation to concentrations exceeding that present in the incubation medium. When sets of slices from six brains were incubated independently in media lacking xylose, subsequent analysis showed that amounts of endogenous material, giving a mean value equivalent to  $10.7 \mu\text{g} \pm 3.1 \mu\text{g}$  xylose/g wet wt. tissue, were present. The experiments reported here involved the incubation of approximately 700 mg of tissue slices, and the slice xylose uptakes of approximately 120  $\mu\text{g}$  at the lowest medium concentration were corrected for the tissue blank. Although the error involved in the calculation of *f* at low medium xylose concentrations is very large, the small amount of endogenous material is insufficient to account for the increase in the tissue cell xylose concentration over the medium concentration. The results are taken to indicate, therefore, that the xylose transport process is an energy-requiring process permitting accumulation of sugar against a concentration gradient. The pronounced inhibition of the xylose uptake of brain cells by anaerobic conditions supports this conclusion.

The effects on xylose uptake of the addition of glucose and 2-deoxyglucose to the xylose-containing medium are also shown in Table 1. Both glucose and 2-deoxyglucose inhibit the uptake of xylose. The possibility that glucose is transported by the same system as the pentose was investigated. Lineweaver-Burk<sup>7</sup> plots of results from experiments measuring xylose-uptakes in the presence and absence of glucose are shown in Fig. 1. The results conform reasonably well to Michaelis-Menten kinetics. When glucose is present the slope of the regression line through the points is increased, but the intercept on the  $1/V$  axis is decreased. The difference between the intercepts of the two lines is not statistically significant, but more precise experiments are necessary to establish unequivocally whether or not glucose inhibits xylose transport competitively. The results give an apparent *K<sub>m</sub>* for xylose of 332 mM and a *V<sub>max</sub>* of 49 mM/l./min. If glucose is assumed to act as a competitive inhibitor the value of *K<sub>i</sub>* is 37 mM. The value of *V* corresponds to a

Fig. 1. Lineweaver-Burk plots of xylose uptake. Each point represents one experiment. The lines through the points were fitted by the method of least squares. The time of incubation with sugar was 4.5 min. Units:  $V$ , mM/l./min;  $S$ , mM/l.

maximal transport rate of approximately 750  $\mu$ M/g wet wt./h, and this is more than adequate to account for the highest rates of glucose utilization observed in cortical slices<sup>8</sup>.

The results presented here strongly suggest that a carrier mechanism of sugar transport operates in brain tissue, and that sugar can be actively transported by this mechanism. Experiments are now in progress to determine other characteristics of the transport system.

### Effect of Norethynodrel on Pituitary Gonadotrophic Potency in Intact Male Rats

THE results described here were obtained during experiments on the mode of action of anti-gonadotrophic substances. They are reported because of the present-day interest in the action of steroids which suppress fertility, and to illustrate how assays of total gonadotrophin may be misleading in this context.

Adult male hooded rats with an average weight of about 350 g were injected subcutaneously with chemically purified norethynodrel dissolved in oil as described by Holmes and Mandl<sup>1</sup>, or with the oil alone. A total of 124 rats was used in six separate experiments in which 0.5 mg

norethynodrel was given daily for 7 days. The rats were killed on the eighth day, when it was found that in all the experiments norethynodrel had caused consistent and statistically significant reductions in the weight of the testes, seminal vesicles and prostate. In two further experiments using 30 rats, 0.1 mg norethynodrel was given daily for 4 days, the rats being killed on the fifth day. This dose caused less striking but still sometimes significant reductions in organ weights.

The anterior pituitary tissue from these rats was homogenized and precipitated as described previously<sup>2</sup>. Saline extracts of the dried material were assayed for follicle stimulating hormone (FSH) by the augmentation method using mice<sup>3</sup>, and for luteinizing hormone (LH) by a method based on published modifications of the method of Parlow<sup>4</sup>. Total gonadotrophin was assayed under the conditions of Brown and Billewicz<sup>5</sup>.

The lower dose of norethynodrel had little effect on the pituitary content of FSH (Table 1). The higher dose produced either little change or a considerable depression of FSH content: no reason for the variability was apparent.

Table 1. EFFECT OF NORETHYNOREL ON PITUITARY GONADOTROPHIC POTENCY

Experiment	Daily dose of norethynodrel (mg)	No. daily doses	Potency per gland of anterior pituitary tissue from rats treated with norethynodrel as % of potency per gland of tissue from control rats (95% fiducial limits)	
			Assayed as FSH	Assayed as LH
1	0.5	7	96 (38-240)	Not assayed
2	0.5	7	128 (74-240)*	170 (83-318)
3	0.5	7	44 (17-94)	Not assayed
4	0.5	7	39 (24-61)	166 (98-300)
5	0.5	7	52 (24-112)	Not assayed
6	0.5	7	51 (23-112)	127 (75-215)
7	0.1	4	106 (45-240)	139 (42-470)
8	0.1	4	87 (39-184)	143 (40-510)

\* This result was based on an assay of 2+1 design. All other assays were of at least 2+2 design.

In five of the experiments LH was assayed and in each case the pituitary tissue from rats treated with norethynodrel was more potent than tissue from rats treated with oil alone. The apparent increase in potency was not great in most instances and in experiments 2, 7 and 8 it was not associated with major changes in FSH content. In experiments 4 and 6, however, a rise in potency as LH accompanied a considerable fall in potency as FSH. The results suggest a change in the ratio of LH to FSH, but in many cases the fiducial limits were wide. Pituitary tissue from the first four experiments was, therefore, tested in the assay of total gonadotrophin to see whether a change in quality of the gonadotrophin might be reflected in a change in the slope of the dose-response lines (Fig. 1). In the first two experiments the lines for tissue

Fig. 1. Log uterine weight is plotted against log dose in the assay of total gonadotrophin. Lines for anterior pituitary tissue from rats treated with norethynodrel (x) are compared with lines for tissue from control rats (●) in experiments Nos. 1 to 4.

from treated and control rats were parallel. In Exps. 3 and 4, however, the lines were parallel at lower levels of response, but at the higher levels the lines for tissue from rats treated with norethynodrel tended to flatten out. This is compatible with an increase in pituitary LH relative to FSH<sup>5</sup>, the situation already suggested by the more specific assays.

These results are consistent with the hypothesis that norethynodrel in certain circumstances may prevent the release of pituitary LH. The findings in the assay of total gonadotrophin confirm a qualitative change in the pituitary gonadotrophin, and illustrate how potency estimates based on this method may be misleading if the design of the assay does not allow the detection of departure from parallelism. A similar and more striking example of this situation has been reported by Rothchild<sup>6</sup>, using material from rats treated with progesterone.

We thank Dr. Bridgett Mason of G. D. Searle and Co., Ltd., for the gift of norethynodrel.

## Phytate Metabolism in Animals

THERE has been interest for some years in the metabolism and availability of phytate phosphorus to animals. It has been reported<sup>1</sup> that phytate phosphorus was not detectable in the gut of ruminants below the reticulum, and it was concluded that micro-organisms were effective in hydrolysing phytic acid and its salts. Faeces of ruminants were capable of inducing the hydrolysis of the phytate of bran when mixed with it, and resulted in a reduction of 16 per cent of the total added phytate phosphorus after 7 days storage at 0° C.

In the case of poultry, the extent and cause of phytate hydrolysis are less well established. Common<sup>2</sup> concluded that phytate was not completely hydrolysed in the alimentary tract of pullets, and this finding has been confirmed for chicks<sup>3,4</sup>. He further showed that the recovery of phytate in the droppings of birds was greater when the diet was supplemented with calcium carbonate than when it was supplemented with calcium phosphate. Work carried out in this Department and in the Department of Agriculture<sup>5</sup> has shown that the recovery of phytate in the droppings of laying birds rises as the percentage of calcium in the diet rises.

Recently an experiment has been reported<sup>4</sup> in which droppings were collected daily and stored cumulatively

for periods up to 7 days at 35° F before analysis for phytate. In order to test whether or not phytate hydrolysis might occur during such a storage period, a bulk sample of droppings from a number of adult (mixed sex) birds was collected within 30 min of voiding, and mixed into a homogenous mass. Two sub-samples of about 3 g each were taken, dried in an oven at 100° C for 24 h, ground in a laboratory mill, and analysed for total phosphorus<sup>6</sup> and phytate phosphorus<sup>7</sup>. Further duplicate sub-samples taken over the following five days from the primary sample, which stood during this time in a loosely covered dish at 50°–60° F, were similarly treated. The initial sample contained 4.83 per cent calcium in the dry matter. The rise in the total phosphorus content suggests that micro-organisms were actively oxidizing organic matter, while the gradual rise in the proportion of phytate phosphorus to total phosphorus suggests that overall hydrolysis was not occurring but that on the contrary slight net phytate synthesis was taking place. The results of this preliminary trial suggest that changes in the total and phytate phosphorus content expressed as percentages of the dry matter and also of the phosphorus distribution, possibly caused by micro-organic activity, may occur if there is an appreciable delay between the time of collection of poultry droppings and their analysis.

This work also supports recent findings<sup>8</sup> that phytate synthesis occurred in the faecal samples collected from chicks fed a phytate-free, casein-gelatin based diet when kept under conventional conditions. When similar chicks were maintained in a germ-free environment, however, the faeces contained no phytate.

## Pancreatic Function during Hypothermia in the Isolated Canine Pancreas

RECENTLY, Véghelyi *et al.*<sup>1</sup> have reported that pancreatic hypothermia leads to diminished pancreatic secretion and diminished enzyme output. Using the isolated denervated canine pancreas<sup>2</sup>, we have been able to perfuse the gland with a cooled perfusate and to analyse the pancreatic secretion for volume and protein output.

As can be seen from Table 1, there is no change in pancreatic juice flow or in protein output when stimulated with 'Pancreozymin' and 'Secretin'.

Table 1. COMPARISON OF NORMAL AND HYPOTHERMIC PERFUSED CANINE PANCREAS

	Normal	Hypothermic
Volume (ml./min)	0.40	0.38
Juice protein (mg./ml.)	68	66

The temperature of the perfusate was 27° C. The gland was stimulated by injection of 25 units of 'Secretin' and 25 units of 'Pancreozymin' obtained from Boots Pure Drug Co., Ltd., Nottingham, England.

These results, when taken in conjunction with those of Véghelyi, would seem to indicate that pancreatic responses to hypothermia are related to neural control. It must be emphasized that the isolated-perfused gland is denervated and that the local reflexes, which Grossman<sup>3</sup> makes mention of, are probably not operative. Furthermore, it is important to realize that the nature of 'Pancreozymin' and 'Secretin' released in the normal intact animal is different from the direct stimulation of the isolated

Table 1. CHANGES IN THE COMPOSITION OF FRESH POULTRY DROPPINGS WITH TIME

Time (days)	Total phosphorus (% of dry matter)	Phytate phosphorus (% of dry matter)	% Phytate phosphorus % Total phosphorus
0.0	1.50	0.368	24.5
0.5	1.52	0.367	24.1
1.0	1.54	0.379	24.5
1.5	1.55	0.379	24.5
2.0	1.62	0.361	22.3
2.5	1.63	0.402	24.7

## PHARMACOLOGY

### Renin-angiotensin System in the Spontaneously Hypertensive Rat

Okamoto and Aoki<sup>1</sup> have reported the separation of a strain of Wistar rats which exhibit spontaneous hypertensive cardiovascular disease. Some of these animals ( $F_2$  by their lineage) have been placed at my disposal, and I have confirmed the occurrence of hypertension in their offspring. I have also determined the activity of the renin-angiotensin system in the kidney by three different methods<sup>2</sup>. The left kidney was grafted on to a rat nephrectomized bilaterally 24 h previously and anaesthetized with pentobarbital sodium (40 mg/kg, intraperitoneally). Pressor activity of the renal venous effluent (renin release) was determined by the pressor response after graft with a definite period (10 min) of interruption of the blood supply to the kidney. The opposite kidney was kept frozen. Pressor activity of the crude extract (renin content) was also determined by injecting it into the bilaterally nephrectomized assay rat. The extract was then acidified to pH 3.0, and incubated at 0° C for 30 min to remove angiotensinase. Various amounts of the pre-treated extract were diluted to 1 ml. and incubated with an equal volume of non-haemolysed rat plasma and M/15 phosphate buffer (pH 6.5) containing 0.002 per cent of thimerosal and  $10^{-5}$  M of ethylenediamine tetraacetic acid at 37° C for 10 min. The angiotensin thus formed was determined by its pressor action in the rat anaesthetized with pentobarbital sodium (50 mg/kg, intraperitoneally) and treated with pentolinium tartrate (5 mg/kg, intravenously). The reaction constant ( $K$ ) was calculated to express the angiotensin-forming activity of renin in the kidney extract.

Four male and two female hypertensive rats, 15-50 weeks of age, with blood pressures of 160-210 mm mercury were examined. Three male and three female normal Donryu rats were used as controls. The rats used for assay were females of the Donryu strain, weighing 200-225 g. The results are shown in Table 1. A similar decrease in activity of the renin system has been found previously in other types of experimental hypertension<sup>3,4</sup> and is consistent with the observed decrease in the juxtaglomerular granulation<sup>5</sup>. Therefore, this investigation adds further support to the concept that renin plays no part in the pathogenesis of hypertension.

Table 1. RENIN-ANGIOTENSIN SYSTEM IN THE SPONTANEOUSLY HYPERTENSIVE RAT

	Control	Hypertensive
Renin release (mm Hg)	25 ± 3.8	13 ± 4.6
Renin content (mm Hg)	34 ± 2.6	21 ± 1.9
Angiotensin formation ( $K \times 10^3$ )	125 ± 13	55 ± 8.9

Figures are mean ± S.E.

### In vitro Interference of Antidepressants with Lipolytic Action of Adrenaline on Adipose Tissue

DURING an investigation of the known antidepressant imipramine ('Tofranil'), this drug was not found to inhibit amino-oxidase, which indicated that this enzyme is not a pre-requisite for antidepressant action<sup>1,2</sup>. The possibility has been raised that imipramine exerts its antidepressive effect by sensitization of a central nervous adrenergic mechanism<sup>3</sup>. Later experiments have shown that among a variety of drugs imipramine markedly reduced *in vivo* concentration of administered tritiated noradrenaline in the heart, spleen and adrenal gland, and concomitantly elevated the plasma level of administered tritiated noradrenaline for the first 5 min. These two facts probably reflected the inhibition of the uptake of catecholamine by tissue caused by imipramine<sup>4</sup>.

Since 1958 rat adipose tissue has been known to respond *in vitro* to catecholamines by enhanced free-fatty-acid mobilization<sup>5</sup>. The question has arisen whether and how this hormonally induced tissue response would be influenced by the presence of antidepressants.

Experiments were carried out with well-known antidepressants, imipramine, norimipramine, amitriptyline, noramitriptyline, including less widely used prothiadene, northiadene and propazepine of similar pharmacological properties<sup>6-11</sup>. In addition, the tranquillizer, chlorpromazine, was included in this investigation. Chemical relationship of all these drugs follows from their structural formulæ:

Norimipramine, nortriptyline and northiadene represent desmethyl derivatives of the parent substances.

Drugs under testing were added into 1.5 ml. of medium (Krebs-Ringer phosphate buffer with neutralized 2 per cent bovine plasma albumin, pH 7.6) where pieces of epididymal fat pad lying proximal to a visible blood vessel, weighing about 100 mg, were incubated. The final concentration of drugs was  $5 \times 10^{-3}$  M or  $1 \times 10^{-3}$  M. Epididymal adipose tissue was excised from bled albino rats. The tissue was incubated while shaking at 38° C for 2 h. Each drug was tested in 6 tissue samples without adrenaline and in 6 samples with adrenaline of final concentration  $3 \times 10^{-5}$  M. The amount of liberated long-chain fatty acids in the incubation medium was determined basically using Dole's method<sup>12</sup>. Means  $\pm$  S.E. are summarized in Table 1. All substances were found to decrease the lipolytic effect of adrenaline. By the decrease of this effect expressed in percentage of control values (Table 2), imipramine and its isomer propazepine are more potent than prothiadene and amitriptyline. What is remarkable is the structure-activity relation between the desmethyl derivatives and their parent drugs, the former having, by far, stronger antiadrenaline action in this simple test.

Table 1. EFFECT OF ANTI-DEPRESSANTS AND CHLORPROMAZINE ON BASELINE AND ADRENALINE-STIMULATED RELEASE OF FATTY ACIDS FROM ADIPOSE TISSUE

	0.005 M	Chlorpromazine	2.23 $\pm$ 0.58	4.43 $\pm$ 0.68	2.20

Table 2. DECREASE OF ADRENALINE-STIMULATED FATTY ACID-MOBILIZATION EXPRESSED IN PERCENTAGE

Drug conc.	Parent substance	%	Monomethyl derivatives	%
	Control	100.0	—	—
	Propazepine	9.65	—	—
	Imipramine	17.5	—	—
0.005 M	Chlorpromazine	20.6	—	—
	Prothiadene	40.0	Northiadene	4.50
	Amitriptyline	47.6	Nortriptyline	1.56
0.001 M	Imipramine	65.9	Norimipramine	14.4

It is well known, and interesting in this connexion, that secondary amines (desmethyl derivatives) are more potent and more rapidly acting antidepressive drugs than their respective tertiary amines at the therapeutic dose. It is thought that desmethylimipramine, accumulated in the brain after demethylation of imipramine, represents the active antidepressive substance, its pharmacological action being dependent on the presence of free catecholamines in the brain. Even when it is hard to decide if the present studies might reflect in some reduced form the complex central stimulating antidepressive action, the results reported here seem to be consistent with the hypothesis that imipramine-like drugs considerably interfere with catecholamine metabolism<sup>4</sup>.

It is to be noted that amitriptyline and nortriptyline have also been found to be active anticholinergic agents. Their pharmacological action has been found somewhat atypical because amitriptyline suppressed salivation at lower doses than nortriptyline and, *in vitro* on guinea-pig ileum, amitriptyline was twice as active as nortriptyline<sup>16</sup>.

Chlorpromazine has been shown here and elsewhere<sup>4,17</sup> to possess similar properties to antidepressants despite its distinct clinical use as a tranquillizer. Bickel *et al.*<sup>18</sup> have shown, however, that tranquillizing and antidepressive pharmacological action is intimately related. Not only imipramine and amitriptyline—weak tranquillizers *per se*—but also phenothiazines, promazine and trifluorpromazine

—strong tranquillizers—could be changed into potent antidepressants by simple demethylation. Since such demethylation process occurs *in vivo*, considerable change of pharmacological properties of parent drugs could be expected if they should be metabolized by different rate and route.

We thank the staff of the Research Institute of Pharmacy and Biochemistry in Prague, Dr. H. Slater of Indianapolis, Indiana, and Dr. W. N. Jones, Lilly Research Laboratories Ltd., Bromborough Port, England, for generous gifts of samples of the tested drugs.

## HAEMATOLOGY

### Platelet Reaction to Adenosine Diphosphate *in vivo*

ADENOSINE diphosphate (ADP) causes agglutination of human<sup>1-3</sup>, cat<sup>4</sup> and rabbit<sup>5,6</sup> platelets *in vitro* and has also been shown to produce a rapid though transient fall in the number of circulating platelets when injected intravascularly<sup>4-6</sup>. Born and Cross<sup>4</sup> postulated that the intravenous injection of the nucleotide led to a drop in the platelet count because "platelets adhere to endothelium and form aggregates which are trapped in the smallest vessels". To test the hypothesis we observed platelet behaviour in small vessels following intravascular injection of ADP.

Transparent rabbit ear chambers were inserted in the left ear of 6 semi-lop-eared rabbits by the method of L'heru *et al.*<sup>7</sup>. Three to four weeks later the animals were anaesthetized with intravenous 'Nembutal' (50 mg/kg initially and 10-15 mg/kg as required afterwards) and the common carotid artery supplying the ear chamber was exposed. A 25-gauge hypodermic needle was inserted in the artery and connected by polythene tubing to a syringe in a slow infusion pump. Infusion of physiological saline was started immediately. Afterwards a  $10^{-2}$  molar solution of ADP (Sigma Chemical Co., St. Louis) in physiological saline (pH 7.3-7.4) was given for 10 min at the rate of 0.28 ml./min and then physiological saline was recommenced. Vessels in the ear chamber were observed at a magnification of 400.

Fig. 1. Platelet aggregate incorporating leucocytes arrested in blood-stream. Flow from left to right. ( $\times 480$ )

All the ear chambers showed mild inflammatory changes characterized by leucocytes 'sticking' in some vessels; most adhered to the endothelium momentarily, but others were attached for long periods. Single platelets, rather than clumps, were found in the marginal blood flow. They adhered to the surface of leucocytes which either stuck to or rolled along the endothelium. Platelets did not roll along the vessel wall and only rarely stuck to the endothelium. When they did, their site of attachment was extremely localized and usually only one adhered. At times 2-5 platelets were attached at the same site, like pins to a magnet, before being swept away. Such were the findings observed during the infusion of physiological saline at the same rate as, or at a faster rate than, that used to administer the test agent.

Within 20-40 sec of commencing the ADP infusion the circulation slowed temporarily. The change varied in intensity from one animal to the next and may have been due to vasodilatation<sup>6</sup> and/or hypotension<sup>4</sup> induced by the agent. Within 2-4 min aggregates of platelets either alone or incorporating leucocytes and erythrocytes were seen in the stream (Fig. 1) adhering to leucocytes and endothelial spikes<sup>8</sup> or impacted in capillaries thereby obstructing flow. Some aggregates were undoubtedly swept into the chamber in the arterial stream, but others formed *de novo* in slow-moving blood columns.

Platelet thrombi and emboli were seen throughout the period of infusion and tended to disintegrate when washed into a fast-moving stream. Platelet adhesion to leucocytes was more frequent, but the tendency to adhere to endothelium was not increased. No morphological change was observed in platelets, leucocytes, erythrocytes or endothelial cells. After ADP infusion ceased blood flow improved and aggregates disintegrated; not all clumps disappeared simultaneously, as occurs *in vitro*<sup>3</sup>. In some instances disintegration was delayed in stagnant and impacted vessels; nevertheless all clumps had usually disappeared within 10 min.

Two animals were given an identical infusion of ADP 0.5 h later and one, a third, 0.5 h after the second. The changes observed were similar though not so prominent and their onset was slightly delayed.

The site of ADP infusion affected the intensity of the observed reaction. Infusion into the femoral or the marginal ear vein of 3 rabbits also caused platelet aggregation in the ear chamber, but it was much less prominent than when ADP was injected into the carotid artery.

In three animals (two with venous infusions and one with a carotid) 0.5 ml. blood was taken from a polythene cannula in the femoral artery at set periods before, during and after the infusion. The samples were collected in glass tubes containing 1 mg dried disodium ethylene-

diamine tetraacetic acid and platelet (Brecher-Cronkite method)<sup>9</sup> and leucocyte counts were made. A 30-50 per cent reduction in platelet count was recorded during the infusion, confirming the work of Regoli and Clark<sup>2</sup>; a parallel drop in the leucocyte count also occurred.

These experiments demonstrate that the intravascular administration of ADP is associated with intravascular agglutination of platelets and also with their adhesion to leucocytes. Platelet thrombi adhere to leucocytes and endothelial spikes and on other occasions become impacted in small vessels, but in the rabbit their adhesion to endothelium is not a prominent feature. The drop in platelet count recorded during ADP infusion is probably due to the trapping of aggregates in blood filters and also to their sequestration in small vessels, as occurs when other substances are injected intravenously<sup>10</sup>, rather than to their 'pavementing' on endothelium. Perhaps the incorporation of leucocytes in the platelet thrombi explains the simultaneous leucopenia recorded in this work.

### Serum Delta-Globulin in the Young Fowl (0-29 Days) and in Other Avian Species

Fowl serum contains a protein which has a lower mobility than  $\gamma$ -globulin in agar-gel electrophoresis at pH 8.6 and was therefore designated  $\delta$ -globulin<sup>1</sup>. This component of serum is exceptional in that it has a molecular weight of only about 20,000 and that prolyl constitutes approximately 12 per cent of its amino-acid residues (Richards, to be published). A method for isolating  $\delta$ -globulin has been described<sup>1</sup>, but it is complicated by the fact that only small amounts of this component are present in adult fowl sera. For this reason, and in view of its unusual characteristics, its occurrence in young birds and in other avian species was investigated.

Immuno-electrophoretic analysis of the sera of young chicks (Fig. 1) showed that  $\delta$ -globulin was present in the serum of the newly-hatched chick and seemed to increase rapidly up to the age of 4 days, although none was found in the 1-day-old chicks. In the case of chicks up to the age of 2 days the sera of several birds were pooled. When sera of older birds, up to the age of 29 days, were investigated, it was found that  $\delta$ -globulin was always present, but the immuno-electrophoretic technique gave no clear indication of the amount in individuals, the occurrence and intensity of the  $\delta$ -globulin line being remarkably variable.

Fig. 2 shows the results of immuno-electrophoresis of turkey, duck, guinea-fowl and pheasant sera, using rabbit antiserum to fowl and turkey sera. A  $\delta$ -globulin line was obtained with guinea-fowl serum but not with the others. Similar experiments with pigeon, quail and goose sera and

Fig. 1. Immunoelectrophoresis of sera of newly-hatched (N.H.) to 4-day-old chicks showing the presence of  $\delta$ -globulin. Rabbit antisera in the troughs:  $a-\delta$ , antiserum to fowl  $\delta$ -globulin.  $a-F/\delta$ , a mixture of  $a-\delta$  and  $a-F$ .

with fowl egg-yolk and egg-white suggested that  $\delta$ -globulin was present in goose serum and in egg-yolk. This does not prove that  $\delta$ -globulin was absent in those cases where a precipitation line was not observed. In order to obtain a reasonably strong line in immuno-electrophoresis of fowl serum it is often necessary to use serum which has been concentrated by a factor of three<sup>1</sup>. No  $\delta$ -globulin line was observed when concentrated turkey plasma was used in immuno-electrophoresis, but absorption of rabbit anti-fowl serum with turkey plasma completely abolished the line produced by the reaction of concentrated fowl serum with unabsorbed anti-fowl serum. It may be that fowl  $\delta$ -globulin has antigenic determinants in common with some other protein of turkey plasma, but it is much more likely that turkey plasma contains a very small amount of  $\delta$ -globulin which has not yet given rise to an observable precipitation line in immuno-electrophoresis. This conclusion is supported by the presence of antibody to  $\delta$ -globulin in rabbit anti-turkey serum; the line given by this antibody with the  $\delta$ -globulin of guinea-fowl is clearly seen in Fig. 2.

Its low molecular weight and its electrophoretic heterogeneity (Fig. 3) suggested that  $\delta$ -globulin might be a molecular fragment of one of the immune globulins. Attempts to demonstrate cross-reactions between  $\delta$ - and immune-globulins have shown no such relation. Sera of

Fig. 2. Immunoelectrophoresis of sera of several species showing the presence of  $\delta$ -globulin in guinea-fowl serum and of antibodies to this component in the anti-turkey ( $a-T$ ) serum.

Fig. 3. Comparative immunoelectrophoresis of fowl serum  $\gamma$ - and  $\delta$ -globulins illustrating the electrophoretic heterogeneity of both proteins.  $a-F$ : rabbit antiserum to fowl serum.

bursectomized fowl in which the amount of  $\gamma$ -globulin was greatly reduced<sup>2</sup> were found to contain as much  $\delta$ -globulin as normal controls.

The presence of  $\delta$ -globulin in the serum of the newly hatched chick and even in the yolk of the new-laid egg, together with its occurrence in other avian species, supports the opinion that  $\delta$ -globulin is a normal component of serum. Its purpose and function have yet to be determined.

### Quantitative Estimation of Human Serum Haptoglobins by an Immunological Method

ALL quantitative estimations of haptoglobin (Hp) are based on the measurement of its haemoglobin- (Hb-) binding capacity, and errors may arise from a decreased or inhibited affinity of haptoglobin for haemoglobin. The results of the peroxidase activity method<sup>4</sup> may be influenced by serum factors inhibiting the peroxidase activity of the Hb-Hp complex. Robert, Bajic and Jayle<sup>1</sup> have been able to show that certain chemical substances, such as heparin and glycine, will not only decrease the affinity of the haptoglobin and the peroxidase activity of the Hb-Hp complex but will also break down Hb-Hp complexes that have already formed. Analogously the influence of serum components on the Hb-Hp complex has been taken as a possible explanation for the often decreased serum Hp level in liver diseases<sup>2</sup>. The development of a method for direct determination of Hp was therefore of interest.

We have been able to estimate human serum haptoglobins quantitatively by an immunological method and to correlate the results with Hp values determined indirectly by the peroxidase activity (activation) method<sup>3,4</sup>. Antisera against human serum haptoglobins were produced in rabbits. Highly purified haptoglobins from a pooled serum containing the different types of haptoglobin prepared by the method of Kluthe and Isliker<sup>5</sup> were used as antigen. In addition we used a preparation which was kindly put at our disposal by Dr. Steinbuch of Paris. Sensitization was started by intravenous injections of the antigen followed by intracutaneous injections with Freund's adjuvant. The development of precipitating antibodies against human Hp was observed by the technique of Ouchterlony<sup>6</sup> and by immuno-electrophoresis<sup>7</sup>. Traces of antibodies directed against other serum proteins were easily removed by absorption with small amounts of a haptoglobinaemic human serum.

For quantitative immunological determination a dilution of the serum was mixed with an excess of antiserum and the amount of antigen-antibody complex was measured by the nephelometric method of Schultze and Schwick<sup>8</sup>. On a number of sera the results were checked by a chemical method (Kunkel and Ward<sup>9</sup>) and good agreement was found. Photometric readings were calibrated against dilutions of the purified haptoglobins.

Fig. 1 shows the results in 82 sera of apparently healthy persons in which haptoglobin was determined simultaneously by the immunological and by the peroxidase activity (activation) method. A linear relationship was observed in concentrations from 25 to 160 mg/100 ml. Differences between the regression coefficients for the three genetically determined types were not obvious.

Fig. 1. Serum haptoglobin in 82 normal sera, determined by the immunological and by the peroxidase activity methods

▲ Renal diseases:  $y = 1.11x - 14.7$ ;  $r = 0.97$   
 □ Liver diseases:  $y = 0.98x + 1.4$ ;  $r = 0.93$   
 ▼ Blood diseases:  $y = 0.85x + 3.1$ ;  $r = 0.97$

( $P(b_{1-1} - b_{2-2}) > 0.1$ ;  $P(b_{1-1} - b_{2-1}) > 0.3$ ;  $P(b_{2-1} - b_{2-2}) > 0.3$ .) The types were kindly estimated by Dr. Hummel, Hygieneinstitut, Freiburg. Similar results were obtained with sera of patients suffering from different conditions which are apt to influence the Hp content of serum (Fig. 2).

Fig. 2. Serum haptoglobin in 51 patients with various diseases, determined by the immunological and by the peroxidase methods

Type 1-1 ○ :  $y = 0.89x + 2.1$ ;  $r = 0.93$   
 Type 2-1 ● :  $y = 0.97x + 4.4$ ;  $r = 0.94$   
 Type 2-2 ● :  $y = 1.06x - 3.3$ ;  $r = 0.96$

The regression coefficient of the pathologic sera as a whole was not significantly different from that of the normal group. Slight differences were observed between the regression coefficients of the renal diseases ( $P = 0.06$ ), the hæmatological diseases ( $P = 0.01$ ) and the normal sera. These findings may be explained by the uncertainty of the determination of very low, and high, Hp values by

the peroxidase activity (activation) method. The good agreement between the immunological and peroxidase activity values in normal sera, as well as in sera from patients with various diseases, strongly suggests that Hp levels measured by indirect methods are actually caused by the real haptoglobin content. Analogously, it is unlikely that low Hp levels in liver diseases<sup>2,3,11</sup> are the result of an impaired formation of the Hb-Hp complex or of chemical inhibition of its peroxidase activity.

The immunological determination of Hp has also a practical importance in measuring very small amounts of haptoglobin. Traces of the protein which give no significant values with the indirect methods could be detected by testing the sera against antiserum in Ouchterlony plates. In hæmolytic disorders with greatly elevated hæmoglobin turnover in which insignificant peroxidase activity was found, the exhaustion of haptoglobin was proved by immunological technique (Kluthe and Heimpel<sup>10</sup>).

### An Improved Amperometric Procedure for the Rapid Determination of Reduced Glutathione in Red Cells

THE determination of sulphhydryl groups in protein by amperometric titration in neutral aqueous solution has been reported by Benesch, Lardy and Benesch<sup>1</sup>. The use of this method for the estimation of glutathione in animal tissue has been considered in detail by Thomson and Martin<sup>2</sup>. One disadvantage of this amperometric titration technique is the transient life of the agar-salt bridge which connects the reference electrode to the reaction vessel containing the rotating platinum electrode. This communication describes a modification of the technique in which the agar-salt bridge is replaced by a ceramic plug which permits direct contact between the reference electrode and the reaction solution. In addition to this, the use of a motor which rotates the platinum electrode at a constant speed has given improved reproducibility of the galvanometer deflexion.

A diagram of the apparatus is shown. The rotator (Mullards, Ltd., London) is connected to the platinum electrode which rotates in *tris* buffer containing potassium chloride as described by Thomson and Martin<sup>2</sup>. The constituents of the reference electrode are the same as those of Benesch *et al.*<sup>1</sup>. The ceramic plug (Electronic Instruments, Ltd., Richmond, Surrey) is in direct contact with the reaction solution. When not in use the platinum electrode is stored in de-ionized water and the plug is covered with a rubber teat filled with the reference electrode solution. Before use the plug is washed vigorously with distilled water.

The apparatus is used for the routine determination of red-cell reduced glutathione as follows: fresh whole blood (0.1 ml. from a finger prick) is added to 0.5 ml. of distilled water and mixed gently to hæmolyse the cells. Sulphosalicylic acid (0.4 ml. of 6 per cent w/v) is added and the

Fig. 1. Diagram of apparatus showing essential components

suspension carefully but thoroughly mixed to precipitate protein material. After standing for 2 min the suspension is centrifuged rapidly and a 0.5 ml. aliquot of the clear supernatant is added to 15 ml. of tris buffer (0.17 M) containing potassium chloride (13 mM) at pH 7.3. The titration is carried out as described by Thomson and Martin using silver nitrate solution (1 mM) dispensed from an 'Aglar' microsyringe fitted with PVC capillary tubing leading directly into the solution. Galvanometer deflexions are plotted against volume of silver nitrate added. The galvanometer deflexions are somewhat greater for a given amount of silver nitrate than those reported in the article of Thomson and Martin.

## PATHOLOGY

### Reversal of Osteoporosis in Lactating Female Rats by Tricalcium Phosphate

PHYSIOLOGISTS as well as astronomers have difficulty in dealing with three bodies, and it is much simpler to consider only two at a time. Calcium, vitamin D and phosphate made bone growth so complicated that paediatricians neglected phosphate. But recently Widdowson *et al.*<sup>1</sup> have shown that phosphate may be a limiting factor. For 40 years, one of us has used the rat, which does not require vitamin D. In the rat, lack of phosphate stops the calcification of bone, but lack of calcium stops the formation of osteoid tissue. Albaum<sup>2</sup> showed that low calcium in the medium caused loss of ATP in bone cultures. Montorsi and Morisi<sup>3</sup> and others have shown that ATP favours the production of osteoid. Osteoid is the characteristic of rickets, and suppression of its pro-

duction by loss of ATP might change the rickets into osteoporosis. A weaned rat, placed on a low calcium diet, shows signs of rickets for a short time only. The rickets change into osteoporosis without a change of diet. To avoid this reversal, we used adults. Chossat<sup>4</sup> showed that a wheat and water diet would produce osteoporosis in birds.

We used lactating female rats so that the demand for calcium would be high, and males of the same age were used as controls. Six lactating female rats and 2 males were placed on the following diet, containing 0.04 per cent calcium: 79 per cent freshly ground yellow maize, 10 per cent dry beef liver, 10 per cent maize oil and 1 per cent sodium chloride.

The two males were each given 250 mg of tricalcium phosphate per day for 110 days and were then killed. Both had normal bones.

The 6 lactating females were kept on the low calcium diet for 60 days, when 3 were killed. These 3 showed basophilia of the bony trabeculae, fibrosis and increased clasmatoctytic activity (all characteristics of osteoporosis) of femur and spine. The degree of osteoporosis varied from 2+ to 3+ on a 4-point scale.

The remaining 3 lactating females were kept for a total of 110 days on the diet, but during the last 50 days were each given 250 mg tricalcium phosphate per day, and then killed. Two of them showed normal structure of femur and spine; the other had osteoporosis to a '1+' degree.

We therefore conclude that it may require about as long a time to cure osteoporosis as to produce it; when 60 days on a low calcium diet was used to produce osteoporosis, 50 days on a high calcium diet cured two rats and almost completely cured the third.

Calcium phosphate was used instead of other forms of calcium because in previous experiments, when calcium lactate or carbonate were used, kidney stones resulted. To flood the body with excess calcium seems dangerous, but when there is enough phosphate to anchor it in the bones or precipitate it in the faeces, the danger is eliminated.

This communication does not discuss human nutrition, except to point out that the addition of calcium to betel nut and coca and maize has not always been noted in the calculation of the calcium intake of primitive people. The boiling of maize in lime water also frees nicotinic acid from non-utilizable combination and prevents pellagra.

### Role of the Rumen Ciliates in Bloat in Cattle

BLOAT (tympanites) in ruminants is characterized by distension of the forestomachs following interference with the normal elimination of gas produced by the microbial digestion of food in those organs. Bloat occurs in cattle usually when fresh legumes are fed, but it may also develop when high-grain rations are supplied in the feed. Many hypotheses have been put forward to explain the ailment, but all have been inadequate in view of its variable nature<sup>1</sup>. Not all animals bloat readily and not all legume pastures produce bloat in susceptible animals.

It appears from experiments carried out in this laboratory that the severity of legume bloat may be partly

determined by the influence of the rumen ciliates on the rate of gas production in the rumen. This work was initiated following the remark of Coleman<sup>2</sup> that Becker<sup>3</sup> and Usuelli<sup>4</sup> had observed that the ciliates of sheep rapidly ingest a large proportion of the starch grains in ground barley and convert them to glycogen. Defaunated animals on the same ration appeared to be bloated, and it was suggested that removal of starch by the protozoa reduced the amount or rate of gas production<sup>5</sup>.

Two pairs of identical twin cows with rumen fistulae were stall-fed on fresh red clover (*Trifolium pratense* L.) at 8.30 a.m. and 1.00 p.m. on weekdays. At night they were kept in a bare yard with free access to water. Before the morning feed the rumen contents were briefly stirred with a hand inserted through the fistula. About 250 ml. rumen liquor was removed, strained through gauze and quickly cooled to 4°. The ciliates were removed from 25 ml. of this sample by centrifuging with a hand centrifuge and washing with buffered solution<sup>5</sup>. The protozoa were finally washed through a 200-mesh sieve. The resulting suspension, which was almost free of plant material, was centrifuged, dried at 100° C and weighed.

The dry wt. protozoa/ml. was plotted against the bloat score as assessed by the method of Johns<sup>1</sup>. Fourteen samples were obtained from the four cows before feeding on six days on which bloat occurred after the first feed. The results for these fourteen samples are shown in Fig. 1.

Fig. 1. Relation between bloat score and weight of protozoa in rumen liquor taken before feeding

A curve of the type  $B = 4.0 - A e^{-CP}$  was fitted, where  $B$  = bloat score (arbitrary scale),  $P$  = protozoa content (mg dry wt./ml.), and  $A$  and  $C$  are constants. The fitted curve was  $B = 4.0 - 1763.9 e^{-1.608P}$ .

It was assumed that the bloat score could not rise above 4.0 and that the scale was linear. The fact that there were discrete steps in the bloat score was ignored.

Fig. 1 shows a significant relationship between the weight of protozoa and the bloat score. The greater the dry wt. protozoa/ml. the more severe was the degree of bloat recorded.

The increase in the weight of protozoa probably resulted from a higher content of ingested food and storage material. Counts of the protozoa were not carried out, but since an earlier survey (unpublished) of the relation between protozoal numbers and bloat did not show an increase in numbers immediately prior to bloat, and since the volume of protozoa collected and weighed varied only between 1.3 and 1.6 ml., the increase in weight probably resulted from a higher content of ingested food and storage material. The presence of ciliates full of food and storage polysaccharide could allow maximum gas production by bacteria following feeding as suggested by the results of Becker<sup>3</sup>. Empty ciliates, on the other hand, could remove relatively large quantities of starch and soluble sugars and delay their fermentation to gas and acids. Reduced acid production

would lower the amount of gas released from the bicarbonate of rumen liquor and reduce the severity of bloat. Protozoa full of storage material could also contribute to the overall gas production by fermenting carbohydrate directly to gas and acid.

It is suggested, therefore, that the rumen ciliates may sometimes influence the severity of bloat, the amount of storage material and ingested food in the protozoa determining the amount of food material available for rapid fermentation to acid and gas. Other factors may also be involved, and work extending the present observations is being carried out.

## ANATOMY

### Organ Size of Human Foetal Bone Marrow

FOR quantitative investigations of haemopoiesis<sup>1</sup>, it is essential to know how much active bone marrow there is in the whole body. Estimates of the 'organ size' of the bone marrow have already been made in animals<sup>2,3</sup>, and similar determinations in the human foetus are relevant to various aspects of foetal haemopoiesis which are being investigated in this department. There seems to have been no previous work on total marrow quantity in the human foetus, although an investigation on three newborn infants has been reported<sup>4</sup>. The following is a summary of my observations.

Material was obtained at routine post-mortem. Fifteen cadavers were examined, of which nine were female and six male. Their body-weights ranged from 1,315 g to 3,720 g, and their approximate maturity, as calculated from body length and from the weight of certain teeth, ranged from 29 weeks to full term. All the foetuses had therefore been 'viable'. No skeletal abnormalities were detected and there was no evidence of pathological states known to exert a specific effect on the haemopoietic system.

It was found possible to estimate the organ size of the bone marrow by a method essentially similar to that used in animals<sup>2,3</sup>. The principle was that of measuring the

Fig. 1. Relationship between marrow volume and body-weight

volume of agar which, following agar-impregnation, occupied the spaces within the macerated skeleton. After correction for the volume of spaces which would not normally contain marrow, the result was taken to represent the total marrow volume. In the foetus, it may all be regarded as actively haemopoietic.

Fig. 1 shows the results plotted against the corresponding figures for body-weight. The data satisfied the requirements for the significance of the linear relationship, the regression coefficient being 0.012 and its standard error 0.0012. In haemopoietic investigations in similar subjects, one might make an approximate prediction of the volume of active bone marrow on the basis of the body-weight. (The amount of haemopoiesis in extra-medullary sites would also have to be considered.) Similar linear relationships were found between the figures for marrow volume and those for estimated maturity, for macerated skeleton weight and for total skeleton volume. The organ size of the bone marrow was, on average, approximately five times that of the spleen.

Of the total marrow, 29.6 per cent ( $\pm$  S.D. of 4.4 per cent) was found in the skull, 23.4 per cent ( $\pm$  2.6 per cent) in the vertebrae, ribs and sternum, and 47.0 per cent ( $\pm$  3.1 per cent) in the limb and girdle bones.

I thank Prof. J. M. Yoffey for advice and Dr. N. J. Brown for providing access to the post-mortem material.

## IMMUNOLOGY

### Inheritance and Properties of the Antigen *MuB1* and its Relation to Haemolytic Complement

WE have previously reported the discovery of an antigen, *MuB1*, which occurs in the sera of certain mice and may be detected by double diffusion in agar of mouse sera against antibody of mouse origin<sup>1</sup>, the distribution of this antigen, *MuB1*, among inbred strains of mice<sup>1,2</sup> and the occurrence of a related antigen in other mammals. We have also given some evidence indicating that mice which lack the antigen *MuB1* do not possess the product of a gene allelic to *MuB1* (ref. 2). The present communication deals with the inheritance of this antigen, its connexion with complement and its properties.

The discovery of an inherited complement deficiency in mice, related to a complement factor *Hc* (ref. 3), has led us to examine the correlation between the antigen *MuB1* and the presence of complement. Tests for the presence of haemolytic complement in mice were made with sheep cells sensitized with very large amounts of antibody as suggested by Rosenberg and Tachibana<sup>4</sup>. By

this test, sera from some inbred strains of mice proved to have haemolytic complement, while sera from mice of other strains lacked it. Its presence or absence was found to be closely correlated with the presence or absence of the antigen *MuB1*. Thus mice of the following strains lacked haemolytic complement, and also lacked the antigen *MuB1*: *A/HeJ*, *AKR/J*, *CE/J*, *DBA/2J*, *RF/J*, *SWR/J*.

The following strains possessed haemolytic complement and the antigen *MuB1*: *BALB/cJ*, *BDP/J*, *BUB/Bn*, *CBA/J*, *C57BL/Ha*, *C57BL/6J*, *C57BR/cdJ*, *C57L/J*, *C58/J*, *MA/J*, *P/J*, *PL/J*, *SL/R1*, *SJL/J*, *SN1/J*, *T6* and *129J*. It is apparent, therefore, that good agreement exists between the presence of *MuB1* and the presence of haemolytic complement. To test this correlation further, hybrids between *MuB1*-positive mice possessing functional haemolytic complement (*C57BL/6J* or *C57L/J*) and *MuB1*-negative animals lacking functional haemolytic complement (*A/J*) were mated with animals of the same strain as the *MuB1*-negative parents (*A/J*). The offspring were tested for the presence of *MuB1* and of haemolytic complement.

Mice of strain *C57BL/6J* are *MuA2*- and *MuB1*-positive; mice of strain *A/J* lack the specificity *MuA2* as well as the antigen *MuB1*. Matings between hybrids *C57BL/6J*  $\times$  *A/J* and inbred mice of strain *A/J* are therefore back-crosses with respect to *MuA2* as well as to *MuB1*, and the offspring of such matings can be used to test for genetic correlation between *MuB1* and *MuA2* (refs. 5, 6). The results of these tests are summarized in Table 1. On the basis of these results it is concluded that the inheritance of *MuB1* is determined by a single dominant gene; that there is no correlation between the inheritance of *MuA2* and the inheritance of *MuB1*, but that there is a highly significant correlation between the presence of *MuB1* and of haemolytic complement.

We next investigated the relation between the concentration of the antigen *MuB1* and the sex and age of various inbred mice by two methods. The first of these was double diffusion in agar, using various dilutions of normal mouse sera placed in peripheral wells, and an antiserum placed in a central well. The reciprocal of the lowest dilution of a normal serum, giving a visible precipitin zone in agar, was taken as an index of the concentration of *MuB1*. Alternatively the quantity of the antigen was estimated in single diffusion, by means of the penetration-distance of the precipitin band into the gelled mixture of agar and antibody<sup>7</sup>. By these techniques it was shown that the content of antigen *MuB1* in sera from male animals is 1.3–2 times as great as that in sera from female animals. These sex-associated differences were found in mice of the following strains: *BALB/cJ*, *BSVS/Sr*, *BUB/Wi*, *C58/J*, *CBA/J*, *DBA/1J*, *MO/Ko*, *SJL/J*, *T6* and *WH/Ht*. The concentration of *MuB1* in mice of strain *DBA/1J* increased as the animals grew from 3 weeks of age to 6 months. This difference, due to age, was much greater in the serum of male than of female animals (Fig. 1). Sex-associated differences were also observed in the number of haemolytic units per ml. of serum from male and female animals. It should be pointed out, however, that the relative (male:female)

Table 1. DISTRIBUTION OF ANTIGEN *MuB1*, HAEMOLYTIC COMPLEMENT (*Hc*) AND SPECIFICITY *MuA2* AMONG THE OFFSPRING OF BACK-CROSSES (Offspring from matings between hybrids of *MuB1*-positive and *MuB1*-negative parents with inbred mice of the same *MuB1*-negative strain as one of the parents)

Italic numbers in parentheses represent values expected on the assumption that there is no correlation between the two characters tested.

Fig. 1. Change in concentration of antigen *MuB1* as a function of age. Mice of strain *DBA/1J*; concentration of *MuB1* measured by single diffusion and expressed as a fraction of the concentration of *MuB1* in the serum of six-month-old male mice of strain *DBA/1J*.

haemolytic potency was not the same as the relative concentration of *MuB1*; in the serum of male mice of strain *BALB/cJ*, for instance, we found five times as many haemolytic units but only 1.4 as much antigen as in the serum of female mice of this strain.

Some properties of the mouse antigen *MuB1* have been investigated. Serum containing *MuB1*, when kept for 17 min at 56° C, loses 50 per cent of its reactivity with mouse antibody. The antigen is insoluble in distilled water and can be found by gel-filtration on Sephadex *G-200* (ref. 8) in a fraction containing molecules of molecular weight 150,000. Since we found that antibody to *MuB1* reacts with a molecule in guinea-pig and human serum<sup>2</sup>, the properties of the guinea-pig and human molecules corresponding to *MuB1* can be explored. These molecules are water-insoluble and are not affected in their reactivity with antibody by treatment with ammonia, hydrazine or zymosan. The guinea-pig antigen loses its reactivity with antibody when heated at 56° C for 1 h. The properties outlined are similar to those of the *C'5* ( $\beta_1F$ ; refs. 9, 10) component of complement and to those of the *C'3d* component of complement<sup>11</sup>.

Two recent papers have dealt with complement deficiency in mice and its correlation with the absence of an antigen<sup>12,13</sup>. Our reported findings<sup>1,2</sup> are in agreement with the strain distribution of the antigen (except for the strains *AKR* and *CBA*), and the mode of inheritance of *MuB1* and *Hc* (refs. 3, 13) is identical with the findings reported here. There is agreement also with the reported sex dependence of haemolytic efficiency<sup>12</sup>. The specificity of antibody to *MuB1* is identical with that of an antibody obtained by Erickson *et al.*<sup>13</sup>, as we have established by an exchange of immune sera with Drs. Herzenberg and Rosenberg.

It seems evident that there is a link between the possession of a functional complement system and the presence of the antigen *MuB1* (ref. 1), but the identity of a complement factor with *MuB1* has, so far, not been established by direct test.

### Role of Complement in Passive Cutaneous Reactions of Mice

PASSIVE cutaneous anaphylaxis (PCA), an immediate type of skin reaction<sup>1,2</sup>, is initiated by combination between cell-fixed antibody<sup>3-7</sup> and antigen, and is characterized by increased permeability of the walls of minute blood vessels of the skin. Whether or not complement plays a part in this increase of permeability is, as yet, not definitively established, though it has been suggested that complement is involved in PCA of the rat<sup>8,9</sup> but not of mice<sup>10</sup> or guinea-pigs<sup>11</sup>.

Recently it has become evident that some strains of inbred mice have a deficient complement system (*Hc*<sup>9</sup>) (ref. 12). The discovery of an antigen *MuB1* (refs. 13-15), detected by a mouse antibody, has allowed the demonstration that the absence of this antigen is correlated with a non-functional complement system<sup>16-17</sup>. This has facilitated an extensive survey of inbred strains of mice for the presence or absence of a functional complement system (*Hc*) (ref. 12), and thus it has been possible to classify mice into *MuB1* positive and complement positive strains and *MuB1* negative and complement negative strains<sup>14-18</sup>.

In the following experiments we have investigated the part played by complement in PCA by comparing the reaction of *MuB1*-positive with that of *MuB1*-negative mice. The antigen chosen for this investigation was bovine pancreatic ribonuclease and the antibody was of rabbit origin<sup>18</sup>. Antibody was injected intracutaneously, and antigen, mixed with Evans blue, was injected intravenously. One hour after the intravenous injection the mice were killed. The skin was removed and the diameter of the blue area on the inner surface of the skin was recorded as the mean of two measurements at right angles. The size of the 'blued' area was investigated as a function of the interval between the intradermal injection of 3  $\mu$ g N antibody and the intravenous injection of 100  $\mu$ g N ribonuclease. In *MuB1*-positive non-inbred *Swiss* mice, the lesion was 5.7 mm when the reactants were injected simultaneously, and 4.8 mm when the antigen was given 180 min after the antibody. In the *MuB1*-negative mice of strain *AKR/J* the lesion was 6.0 mm if the reactants were injected simultaneously

Fig. 1. Changes in the mean diameter of 'blued' areas observed in *MuB1*-positive Swiss mice and *MuB1*-negative mice of strain *AKR/J* as a function of the interval between the intradermal injection of  $3 \mu\text{g}$  *N* antibody and the intravenous injection of  $100 \mu\text{g}$  *N* antigen. Antigen, bovine pancreatic ribonuclease; antibody, raised in rabbits; mean diameter of 'blued' area observed in the skin of six-week-old, male animals. ●, Swiss mice (*MuB1*-positive); ○, mice of strain *AKR/J* (*MuB1*-negative).

but was not demonstrable if the interval between injections was longer than 2 h (Fig. 1). If the larger doses of antibody were injected the 'blued' area could be observed in *MuB1*-positive and *MuB1*-negative animals if the interval between the two injections was much longer, but the relative difference between the action of *AKR/J* and Swiss mice remained the same. On the basis of these experiments, mice from three additional strains of *MuB1*-positive animals (*BALB/cJ*, *BUB/Bn* and *SJL/J*) and mice from three additional strains of *MuB1*-negative animals (*AHe/J*, *RF/J*, *SWR/J*) were injected intradermally with  $3 \mu\text{g}$  *N* antibody and were given, 3 h later, an intravenous injection of ribonuclease ( $100 \mu\text{g}$  *N*). Whereas the *MuB1*-positive animals responded with blued areas 8.8–5.5 mm in diameter, the *MuB1*-negative animals did not give a significant response.

It is therefore clear that a permeability increase can be observed in *MuB1*-positive mice if an interval of 3 h is allowed between the intradermal injection of antibody and the subsequent intravenous injection of antigen, and that this reaction is not observed in *MuB1*-negative mice. We investigated, next, whether the difference in the response of the two groups of mice was attributable to a humoral factor. To this end, *MuB1*-negative mice of strain *AKR/J* were injected intradermally with antibody ( $3 \mu\text{g}$  *N*) and 3 h later with a mixture of ribonuclease, Evans blue and the serum from *MuB1*-positive animals (*BALB/cJ*, *CBA/J*, *C57BR/cdJ*, *C57L/J*, *C58/J*, *MA/J*, *PL/J*, *SL/R1*, *129/J*, *C57BL/6J*). Under these conditions 'blued' areas were observed. 'Blued' areas did not occur if sera from animals lacking *MuB1* (*AHe/J*, *CE/J*, *DBA/2DeJ*, *RF/J*, *SWR/J*) replaced the *MuB1*-positive sera in the aforementioned procedure.

It had thus been demonstrated that a humoral factor is involved in PCA and that this factor is present in the serum of *MuB1*-positive but not of *MuB1*-negative animals. It was also possible to supply the humoral factor, required for the permeability increase, by the injection of fresh, but not of heated ( $56^\circ$ , 1 h), guinea-pig serum. In fact, a unit volume of fresh guinea-pig serum was five times as effective as a unit volume of fresh serum from Swiss mice.

The permeability increase, caused by the simultaneous injection of antigen and antibody, is the same in *MuB1*-positive and *MuB1*-negative animals. On the other hand, the permeability increase, occurring when antigen is given some hours after the intradermal injection of antibody, depends on the presence of a humoral factor which is present in the serum of *MuB1*-positive but not of *MuB1*-negative mice. It would thus seem reasonable to conclude that two different reactions are involved in permeability increase. The first of these may involve antibody not fixed to cells or antibody which fixes to cells very rapidly.

The second reaction depends on relatively slow fixation of the antibody to cells and should therefore increase after prolonged residence of antibody in the skin. A humoral factor, most probably complete haemolytic complement, is involved in the second, but not in the first, reaction. However, the two reactions occur simultaneously, their relative importance depending on the quantity of antibody and the interval between the injections. Contradictory results in the literature may be attributable to the differences in the properties and concentration of different types of antibodies, but also to differences in the relative contribution of the two reactions as a function of the quantity of antibody and the interval between injections of the reactants.

## RADIOBIOLOGY

### Dose Ratio of X-rays to Fast Neutrons in producing Dominant Lethals in Flour Beetles, *Tribolium castaneum*

GENETIC effects of radiations of varying relative biological effectiveness on germ cells in different stages of development and differentiation have been examined in mice<sup>1,2</sup> and *Drosophila*<sup>3,4</sup>. The authors found similar relative biological effectiveness values on the basis of radiation-induced dominant lethals (50 per cent) or recessive lethals. Earlier work<sup>5</sup> showed that the frequencies of fast neutron-induced chromosome aberrations (a measure of relative biological effectiveness) were similar for *Drosophila* and *Tradescantia*.

This communication reports the 'dose ratio'<sup>6</sup> of 250-kV X-rays and fast neutrons of mean energy 4.6 MeV for 50 per cent dominant lethals in flour beetles, *Tribolium castaneum*, observed during two weeks post-irradiation. Detailed examinations of X-ray and fast neutron radiation effects on productivity of this species of flour beetles will

be reported elsewhere'. 'Dose ratio' is a more appropriate term than 'relative biological effectiveness' in evaluating these findings, since dose-response curves (dominant lethals) were of the 'multi-hit' type curves for X-ray and 'one-hit' type for fast neutrons. Such curves cannot be compared for relative biological effectiveness calculations because of their different slopes.

Fast neutrons were 2-3 times more effective than X-rays in producing 50 per cent dominant lethality (Table 1). Although only a single fast neutron exposure (830 rads) was given, the dose-response curve (per cent dominant lethals) was extrapolated through it to the origin in order to obtain the radiation exposure which induced 50 per cent dominant lethals. This curve seemed justified for three reasons, namely: (1) the proximity of observed dominant lethal per cents in male- and female-exposed groups to 50 per cent; (2) the linear dose-response curves for fast neutrons from other works<sup>3-5,9</sup>; (3) similar dose ratio values were calculated by determining the X-ray dose which caused the same effect as 830 rads of fast neutrons (Table 1, last column).

Table 1. DOSE RATIOS FOR DOMINANT LETHALS INDUCED BY 250-KVP. X-RAYS AND 4.6-MEV FAST NEUTRONS IN FLOUR BEETLES, *Tribolium castaneum*, CULTURED AT DIFFERENT TEMPERATURES FOR TWO WEEKS

Temperature (C)	Sex exposed	Dose ratio for dominant lethals 50% effect (calculated)	830 rads effect* (observed)
25	♂	2.7	2.6
	♀	2.6	2.7
	♂♀	2.8	2.6
29	♂	2.5	2.5
	♀	2.3	2.4
	♂♀	2.1	2.2
32	♂	1.8	2.4
	♀	1.9	2.2
	♂♀	2.5	2.4

\* Rads of X-ray to obtain fast neutron effect  
Observed effect at 830 rads of fast neutrons

Dose ratio values were comparable regardless of sex exposed or temperature. The mean dose ratio of 2.4 which represents the response of all meiotic stages at the time of irradiation is similar to that of 3.4 for *Drosophila* calculated from the data of Alexander<sup>3</sup>; corresponding relatively biological effectivenesses for the latter were 1.6, 2.3, 3.2, 3.1 and 6.6 for meiotic through sperm stages. Ionizing radiations would be more hazardous to pre-meiotic or meiotic cells than to post-meiotic stages because the latter are of brief duration and therefore subjected to fewer chances for irradiation.

In conclusion, to obtain similar frequencies of dominant lethals, X-ray doses 2-3 times higher than those for fast neutrons exposure were required. The mean dose ratio of 2.4, which produced 50 per cent dominant lethals in *Tribolium*, corresponds with the value of 3.4 in *Drosophila*, for which relative biological effectivenesses (dose ratios) at particular spermatogenic stages were known.

## Circulating Stem Cells: Variation with Duration of Partial Body X-irradiation

LEUCOCYTE depression is often produced by localized radiation therapy. This frequently appears inordinate for the amount of bone marrow within the radiated field. A possible explanation for this leucopenia is that during a course of radiation therapy (usually given in daily doses for a number of weeks) a large number of circulating stem cells<sup>1-6</sup> enter the radiated field, are destroyed, and thus a leucocyte depression is produced. I have attempted to test this hypothesis in previous experiments<sup>7,8</sup> by subjecting two groups of mice to partial body irradiation. Both groups received the same total dose; however, one group was radiated for 2-3 min while the other was exposed for 100-120 min. If the hypothesis is correct, then the mice exposed for the longer duration should develop a more profound and prolonged leucopenia. This is what was observed. The present experiment attempts, more directly, to observe the effects of the duration of partial body irradiation on the number of circulating stem cells to see whether these changes in the leucocyte levels reflect changes in stem cells.

Till, McCulloch *et al.*<sup>9-12</sup> have demonstrated that intravenously injected bone marrow cells will form discrete colonies in the spleens of mice previously receiving lethal doses of whole-body irradiation. These colonies contain various immature hematopoietic cells and appear to be derived from single cells<sup>10</sup>. The number of spleen colonies is thought to be proportional to and can be used to assay the number of stem cells in the injected bone marrow. Recently, it has been shown that peripheral blood contains cells capable of colonizing the spleen<sup>6</sup>.

In this experiment mice were exposed to 900 r. with the left lower extremity shielded. It seemed possible that stem cells from the unirradiated extremity would circulate, and colonize the spleen. The number of colonies could then be used to assay the number of stem cells coming from the unirradiated extremity. The duration of radiation exposure was varied. If the hypothesis is correct, then the more protracted irradiation would allow more stem cells to circulate from the shielded limb into the remainder of the body during the radiation period, be sterilized and, therefore, the number of spleen colonies should decrease with increasing duration of radiation.

Female 3-5 months old C3H/CGRL mice bred in this laboratory were used for this experiment. All the mice were anesthetized with 1 mg of sodium pentobarbital, 6 mg of tribromethanol and 3 mg of amylene hydrate intraperitoneally. They then received 900 r. with the left lower limb shielded by 3 × 5 cm sheet of lead 2.5 mm thick. The radiation factors were: 250 kV X-ray with 2 mm aluminium filtration, half-value layer 0.8 mm copper. The dose was measured in air at the radiation distance with a Philips (R) Universal dosimeter, and the output was monitored during radiation. The dose rate was changed by varying the distance from the radiation source (from 33-162 cm) and the current (7-19 m.amp). Surviving mice were killed 9 days following radiation, the spleen removed and, after fixation in Bouin's solution, macroscopically visible colonies were counted.

Control animals received the same dose of 900 r. with no limb shielding and spleen colonies were counted in a similar fashion. These animals (15 in each group) receiving 900 r. whole-body radiation without limb shielding demonstrated a mean spleen colony count of 0.46 (± 0.09) when the radiation duration was 1.4 min. When the duration was extended to 86 min, the mean spleen colony rose to 3.3 (± 1.6). This demonstrated the usual and expected dose rate effect, the high intensity short duration radiation being more effective<sup>13-17</sup>.

Fig. 1 shows the mean number of spleen colonies in mice receiving 900 r. with one limb shielded plotted against the duration of irradiation. With increasing duration the number of colonies decreased. The statistical

Fig. 1. The mean ( $\pm$  S.E. mean) number of spleen colonies in mice nine days after 900 r. with left lower limb shielded plotted against the duration of radiation. The number of mice in each group is in brackets

significance of these differences is shown in Table 1. These results are consistent with the hypothesis that stem cells do circulate from the unirradiated limb and colonize the spleen. The more extended radiation time allows a greater number to enter the field during the radiation period and be sterilized and, therefore, fewer stem cells remain available in the non-irradiated extremity to form spleen colonies later.

Table 1. MEAN NUMBER OF SPLEEN COLONIES OBSERVED IN ANIMALS EXPOSED TO 900 R WITH LEFT LOWER LIMB SHIELDED

Radiation duration (min)	Spleen colonies ( $\pm$ S.E. mean)	Diff. from 1.4 min	P value of diff.
1.4	25.2 $\pm$ 2.4	—	—
4.2	23.9 $\pm$ 2.2	1.3	—
9.0	19.2 $\pm$ 2.3	6.0	0.1-0.05
30.0	16.7 $\pm$ 1.6	8.5	0.01-0.001
60.0	15.3 $\pm$ 1.2	9.9	< 0.001
86.0	13.9 $\pm$ 1.7	11.3	< 0.001

If the rate of release of stem cells by the unirradiated limb is constant, then a linear function should be described in Fig. 1. This was observed by Hanks in a somewhat different experiment<sup>18</sup> using longer time-periods. It is of interest to speculate about a possible explanation for the observed deviation from a linear function. It seems reasonable to assume that the number of stem cells able to circulate and colonize the spleen from the unirradiated limb is limited. Since the remainder of the body is being irradiated, the number of viable cells entering this limb is then being depleted by egress without compensatory entry of viable stem cells. This would explain the prompt reduction in colonies which then gradually tapers as the pool becomes exhausted. This rapid reduction in size of pool would suggest extensive migration of stem cells from marrow sites into the peripheral blood. An alternative possibility is that in the normal steady state migration is not this extensive but rather that radiation in some way accelerates the release of available stem cells from unirradiated areas.

Complicating the interpretation are considerations of cell recovery from irradiation. With whole-body radiation more spleen colonies were found when the radiation was protracted. This is consistent with the generally observed decrease in effectiveness of a given dose of radiation as dose rate is reduced. When the limb is shielded, one would expect the same dose rate effects, and therefore the more protracted radiation would be less effective. This would tend to flatten the curve as the dose rate is decreased and counteract the initial rate of reduction of colony-forming units.

Further experiments are in progress to try to elucidate these problems. It seems clear, however, that cells able to form spleen colonies do circulate, and protracted localized irradiation allows time for a greater number to be destroyed.

I thank Miss Helen Grate for her assistance, Dr. M. M. Kligerman for support and advice and the U.S. Public Health Service for financial support (CA-C 6519 and 5TL-CA 5094).

## BIOLOGY

### Productivity of the Bassin de Chasse in Ostend

IN view of the increased interest in the possibility of marine fish farming, the following observations of high primary production and high growth rate of molluscs in a semi-natural lagoon in Ostend suggest a simple approach to this problem.

It will be recalled that there have been two main lines of approach to the problem of fish farming. The early fisheries biologists saw that the fecundity of the food fishes was high, but that there was a very high mortality of eggs and young larvae. They thought that by reducing this mortality they could increase the numbers of fish reaching the adult fish population. They, therefore, sought to rear young fish through the critical period and to release them subsequently to the sea. To affect the stock in the sea the number released would have to be very high and the fish would have to be sufficiently robust to survive the transfer and to compete for food with the natural population. Expensive hatcheries were required for this work and great control of the food supply and the environment in the tanks was necessary. Only now has Shelbourne<sup>1</sup> succeeded in bringing such work to a stage when mass production of one-year-old plaice from a 'fish factory' becomes possible. Ideally, these fish should be released into a rich environment so that a growth rate higher than that in a wild population is achieved.

The work of Gross<sup>2</sup> and his collaborators was aimed at increasing the productivity of a restricted sea area so that the growth rates of the fish would be increased. To this end great quantities of phosphates and nitrates were poured into two sea lochs. In both cases a high zooplankton production was recorded. However, the main benefit from the increased production went to benthic animals and sub-littoral algae. Growth rates of plaice and flounders were increased about four-fold but, apparently because the growing fish migrated from the lochs, the

experiments did not indicate that such a scheme would be economic<sup>3</sup>.

A similar experiment by Buljan<sup>4</sup> in Yugoslavia was rather more successful. Here, 'fertilization' was aimed at increasing the growth rates of oysters and mussels. There were increases of some 20 per cent and 30 per cent, respectively, in the seasons following 'fertilization'. In the Bassin de Chasse in Ostend the natural growth rates of oysters and mussels are as high as those obtained after such procedure.

The Bassin de Chasse<sup>5</sup> is an artificial lagoon enclosed by a brick retaining wall and covering an area of some 86 hectares. To the west it opens by a main sluice into Ostend harbour and on the south side three small sluices communicate with a branch of the Bruges Canal. The average depth of water is between 1 and 1.5 m and its level can be regulated by opening or closing the sluices. The bottom is partly of soft black mud, but towards the east the proportion of fine sand increases until at the extreme eastern end there is pure sand in places.

Attempts at oyster cultivation<sup>6</sup> in the lagoon were made from 1933 to 1939. Successful breeding and growth of spat was obtained in 1938, but the war prevented marketing of these oysters. During the war a dam was built across the western end of the basin, sealing off the main sluice. It was then used as a sea-plane base. From 1942 to 1955 it remained out of communication with the sea. Attempts at growing oysters were not successful and in 1956 the dam was removed, enabling the basin to be fully drained.

Young Dutch oysters are cultivated by cementing them on to greenheart stakes which are suspended vertically from platforms. The oysters are put out in the basin in March or April and are harvested for sale, beginning in August and continuing into the early winter. At this time the water is released and the basin is allowed to remain dry during the winter. In the following March the basin is refilled by raising the sluice gate at high water. Leloup<sup>6</sup> has shown that in the harbour there is a tongue of high salinity water close to the bottom and it is this water which is used to refill the basin in spring, when the oysters are planted out.

The oysters show very high growth rates, as can be seen in Fig. 1(a). This high growth rate is not merely a linear shell shoot; the indices of quality are high. Mean indices of quality<sup>13</sup> for the 1960 and 1961 seasons were 113.24 and 114.88, respectively. For comparison, the growth<sup>4</sup> of Yugoslavian oysters before and after the 'fertilization' experiments is also shown. The oysters from the western end of the Bassin de Chasse have a higher growth rate than even the experimentally augmented Yugoslavian oysters.

Walne<sup>6</sup> investigated the effects of tidal exposure on the growth of oysters at Conway. He showed that a 50 per cent difference in growth increment occurred between oysters experiencing 1.5 per cent and 14 per cent exposure. In other words, the oysters in deeper water with less exposure to air had greater growth. Part of the explanation of the high growth rate in the oysters of the Bassin de Chasse may then lie in their lack of exposure.

Fig. 1(b) gives a comparison of the growth of *Mytilus edulis* from the Bassin de Chasse<sup>6</sup>, Vigo<sup>7</sup> and Menai Straits (Davies, personal communication). The three sets of data all refer to mussels grown under water. Those from Vigo are cultivated on ropes hung from floating platforms in deep water. Andreu stated that their growth rate was the highest recorded in Europe. The data from Menai Straits refer to some experiments with mussels grown on horizontal plastic mesh trays, 1-2 ft. below the surface of the water. The data from the Bassin de Chasse give the growth from the time of settlement of mussels on the oyster stakes.

From these two examples alone, it is evident that the Bassin de Chasse is an area of high productivity. Indeed, one of the major problems in oyster cultivation has been the enormous production of competitors such as

Fig. 1. (a) Growth rates of oysters from the Bassin de Chasse, Ostend, and of Yugoslavian oysters. (b) Growth rates of mussels from the Bassin de Chasse, from Spain and from North Wales

*Crepidula fornicata* and parasites such as *Polydora*. Polk<sup>10</sup> showed that in five months a length of 24.1 mm was recorded for *Crepidula* and that at four months some were already incubating eggs. Walne<sup>11</sup> reported, from data of *Crepidula* in the River Crouch, that a mean length of about 8 mm was reached by their first winter, and 14 mm at the end of their second winter. Females were spawning when about four years old. Again we see high growth rates in the basin. Noting that *Crepidula* larvae did not appear to survive outside the basin, a technique<sup>12</sup> by which the basin was emptied at peak *Crepidula* spawning was developed. In 1961 the basin water was changed four times during May and June. The observed settlement on 804 test plates was 17 individual *Crepidula*, compared with 15,746 on 828 plates in 1960. This technique might be further used in reducing the infection of *Polydora*.

The high growth rates of molluscs must be maintained by a high level of primary production. It is interesting to compare the quantities of copepods and phosphates in the basin compared with other areas. Leloup and his colleagues record a maximum number of copepods and nauplii of 685 per litre<sup>13</sup>. This compares with 600 per litre in the 'fertilized' sea loch and a maximum of six per litre in the 1948 plankton catches off Flamborough Head; however, these latter catches do not include nauplii. In the basin

and in the 'fertilized' loch it is interesting to note that the same species are involved, namely, *Temora longicornis* Müller, and *Centropagus hamatus* Lillj. In addition, *Acartia biflosa* was abundant in the basin.

The 1960 maximum phosphate level recorded in the basin was 1.197 mg/l. compared with a maximum of 0.1302 mg/l. obtained in January 1962 from a station in the North Sea near Ostend (P. G. W. Jones, private communication). In August 1954, a value of 1.535 mg/l. was given by Leloup. It is evident that there is a high phosphate reserve in the basin, as at that time there had been no direct communication with the harbour for 12 years.

The mechanism by which such high productivity is maintained has not been fully investigated. Under the conditions where the water is held in the basin from March until winter, death and decomposition of the annual plankton production returns the nutrients to the basin. But, unlike the sea loch experiments, where some nutrients remain permanently locked up in algae and benthic animals, many of these are killed by exposure to frost when the basin is drained in the winter. Perhaps the mud acts as a store of nutrients. In this connexion, it is interesting to note that Polk has observed that the growth rates of oysters in the western portion of the basin, where they lie over mud, are higher than those in the east where sand is present.

The Bassin de Chasse, with its sluices and shallow water, would seem to afford an ideal situation for a full study in basic productivity. As well as providing rich fattening grounds for oysters, where parasites and commensals are controllable, such areas might also be adapted for fish farming.

### Blue Pigment of a Surface-living Oceanic Copepod

THE development of special nets has made it possible to sample specifically the plankton living in the uppermost layers of the sea. Routine sampling with such a net, designed by P. M. David at the National Institute of Oceanography, to fish only in the top 4 in. of the water, has been carried out during the present cruise of the R.R.S. *Discovery* in the Indian Ocean. One of the most striking features of the living hauls is the predominance of blue pigmented organisms, and these have been seen in a wide diversity of groups, among them copepods, mysids, decapods, stomatopod larvae, siphonophores, chaetognaths, salps, doliolids and appendicularians. The most typical members of the catch are pontellid copepods, and these show a blue colour more intense than most other groups. Since blue is a colour almost completely absent in deeper-living plankton, it was considered to be of interest to make a closer examination of this typical feature of the tropical surface plankton. Using the surface net it was possible to capture very large numbers of *Pontella fera* Dana and carry out a simple analysis of its pigment.

Three surface hauls were made in different regions and a few hundred *P. fera* were either picked out individually or, on one occasion when several thousands were caught, the other components of the catch were removed. Having separated animals of both sexes, excess water was removed on filter paper, and the animals were ground up with a little distilled water until a satisfactory homogenate was obtained. Further distilled water was added, and the suspension was centrifuged for 10 min at approximately 4,000 r.p.m. This caused a layer of solid carapace pieces to separate out at the bottom, above it a fatty layer, and above this an opaque blue liquid. This supernatant liquid was pipetted off and filtered through a Whatman No. 42 filter paper, the solids being discarded. The filtered liquid was a clear blue solution which was very stable on one occasion but rather more unstable on the two subsequent occasions, tending to precipitate out after some time. This is probably due to changes of pH occurring in the solution. The blue solution was examined in a spectrophotometer between 400 and 1,000 mμ using a 1-cm cuvette—the high organic content of the solution ruling out any useful examination in the ultra-violet region. The result is given in Fig. 1A, the curves being almost identical on each occasion, and showing a broad absorption band with a peak at about 640 mμ.

The blue pigment is insoluble in ether, benzene and carbon tetrachloride, and treatment with these agents accentuates the peak but does not alter its position. Treatment of the blue pigment with alkali, organic or mineral acids, alcohol or acetone permanently decolorizes it, giving a reddish-yellow solution, the characteristic absorption curve of which is shown in Fig. 1B. The blue colour is similarly lost on heating the solution slowly to about 65° C. After freezing the solution, precipitation occurs when it is subsequently thawed. Passage through activated charcoal completely removes the colour of the solution. When the pigment is allowed to decay by standing for a day or more there is a tendency for a transient greenish tinge to appear and the solution becomes cloudy.

It seems probable that the pigment is a chromoprotein complex of a carotenoid and a protein. This is suggested by its initial insolubility in fat solvents, the ease by which it is denatured, particularly when pH changes occur, and the fact that the peak absorption after denaturation (presumed to involve breakage of the carotenoid-protein link) is at 450-475 mμ, a region characteristic of the carotenoid pigments commonly found in planktonic animals. In the living animal the pigment appears to be uniformly distributed over the body, both in the exoskeleton and in the underlying epidermis. There are three main sites where it appears to be more concentrated, namely, the thickened

Fig. 1. Spectral absorption of the initial extract of blue pigment (curve A) and after treatment with citric acid (curve B).

Fig. 2. Spectral energy curve of the upward illumination at the Swedish Deep Sea Expedition station 192 in the eastern Indian Ocean (after Jerlov)

grasping portion of the male right antenna, on the inside of the base of the first antennæ in both sexes, and over the ventral eye. The latter, particularly, appears deep blue, but dissection shows that a thickened layer of deep blue chitin overlies a red fat-soluble pigment spot.

The reason for the preponderance of blue in the tropical surface plankton is not immediately clear. The background colour of clear oceanic water is a deep blue, as can be seen from Fig. 2, showing the spectral energy of upward illumination at 2 m depth at the Albatross station 192 in the eastern Indian Ocean according to Jerlov<sup>1</sup>. It will be noted that the spectral transmission of the pigment is relatively high over the same region and only decreases at about 550 mμ, above which the background energy is exceedingly low. The pigment, therefore, transmits the ambient light with little wave-length change and the animal matches the background very well. This will only apply when it is viewed from above or from the side, but the main predators of surface-living copepods are probably flying-fish which are found at approximately the same horizontal level. Similarly, the blue of *Porpita* and other siphonophores may be a camouflage for the predator. This argument, however, would not seem to hold good for animals which are more usually transparent, for example, the chaetognaths, stomatopod larvæ and doliolids. In some species, such as the copepods, it may be that there is an obligatory accumulation of carotenoids, the basic red colour of which is masked by the linkage with a protein so that the animal becomes much less conspicuous.

The diffuse distribution of the pigment in almost every case, and its appearance in widely separate taxonomic groups, makes it seem more likely that it is, as Heinrich<sup>2</sup> has suggested, a protection against the strong solar radiation to which the tropical surface plankton is exposed. The ultra-violet wave-lengths are generally considered as the most biologically harmful, but it is not known whether the blue pigments do strongly absorb these wave-lengths. Though the penetration of the longer wave-lengths, particularly the infra-red, is very small, they may be an important factor in the top few inches of the surface of the sea, and the pigment with the peak absorption at 640 mμ would screen the organs from much of this energy. None of these explanations seems wholly satisfactory, however, and it is hoped that further work will make the reasons clearer. Preliminary work on another species of *Pontella* has given similar results and it is hoped to carry out further analysis of the pigment of this and other species of surface plankton.

I thank Mr. R. I. Currie and Mr. P. M. David for their interest and assistance in this work.

## Variable Toxicity of Triazine Herbicides

WHEN applied to the soil surface several triazine herbicides have been shown to be toxic to gymnosperm seedlings, with older seedlings much less susceptible than young ones<sup>1,2</sup>. The method of herbicide application also greatly influences the toxicity of triazines. For example, no injury occurred to 2-year-old *Pinus resinosa* plants when simazine was applied to the soil surface at 4 or 8 lb./acre or when applied to the foliage only. However, incorporation in the soil of simazine applied to the soil surface caused severe injury and high seedling mortality<sup>3</sup>. The triazine herbicides apparently are less toxic when applied to the soil surface than when incorporated in the soil because they do not leach readily and, in the former case, roots of trees often are below the soil layers containing phytotoxic amounts of these chemicals. For these reasons differences in actual toxicity of different triazines may not be readily apparent when the herbicides are applied to the soil surface. Experiments have now been extended to evaluate the effects of several soil-incorporated triazine herbicides on development of young *Pinus resinosa* seedlings.

Herbicides tested included simazine, atrazine, propazine, prometryne and ipazine. Plainfield sand was placed in greenhouse flats to a 2-in. depth and the appropriate herbicide sprayed on the soil surface at 2, 4, 8 or 16 lb./acre. The soil and herbicide were then mixed in a Patterson-Kelly twin shell blender and distributed into cylindrical, one-pint paper cartons with holes in the bottom for drainage. One hundred *Pinus resinosa* seeds were planted in each of 10 cartons for each dosage of each herbicide. Ten cartons of mixed soil planted with seed but without added herbicide served as controls. The cartons were placed on a greenhouse bench and watered daily. Toxicity symptoms and survival counts were noted periodically. 110 days after planting the living seedlings were counted and their tops clipped off at the ground line for dry weight determinations.

Table 1. MEAN DRY WEIGHTS OF SHOOTS OF LIVE SEEDLINGS 110 DAYS AFTER HERBICIDE TREATMENT (PER CENT OF CONTROL)

Dosage † (lb./acre)	Atrazine	Simazine	Herbicide Prometryne	Propazine	Ipazine
2	0*	12.2*	19.8*	81.0	100.0
4	7.9*	8.5*	17.9*	81.7*	138.3
8	0.2*	5.3*	0*	12.8*	75.6
16	0.2*	0*	0*	0.2*	21.6*

\* Sig. diff. from control at 1 per cent level.

† Herbicide applied to soil surface at indicated rate and then incorporated into soil.

In general, toxicity to pine seedlings varied greatly among herbicides with atrazine the most toxic and ipazine the least. Within 10 days after germination variable herbicide toxicity was evident, with atrazine, simazine, and prometryne injury already apparent at the higher dosages. Neither ipazine nor propazine injury was observed at this early stage. Early toxicity symptoms included slight needle curling, chlorosis, and growth inhibition. The symptoms became more severe with time and later were apparent at low dosages of atrazine, prometryne and simazine. All, or virtually all, seedlings were killed within 110 days after planting by the two highest dosages of atrazine and prometryne and the highest dosages of simazine and propazine (Table 1). Atrazine was highly toxic at all dosages, while prometryne was far more toxic at the two highest dosages than at the two lowest ones. Propazine was only mildly toxic at low dosages but very toxic at the highest dosage. Ipazine was very toxic only at the highest dosage. Especially interesting was the accelerated late mortality under certain treatments. Ipazine, for example, caused no readily apparent damage at any dosage 80 days after planting. In the next 20 days, however, toxicity symptoms developed very rapidly in plants treated with ipazine at the highest dosage. This emphasizes the importance of investigating herbicide toxicity over relatively long

periods of time. This would seem to be especially important in the case of triazine compounds since they do not leach or degrade rapidly<sup>3,4</sup>.

### Modifications of the Agar Film Technique for assaying Lengths of Mycelium in Soil

CRITICAL analysis of methods for assaying lengths of fungal mycelium present in unit weights or volumes of soil<sup>1</sup> has shown that the agar film technique<sup>2,3</sup> is least prone to experimental error. The technique has been used successfully in these laboratories for a number of years, and a number of slight modifications have proved useful in eliminating accidental errors and increasing the reliability of the technique. These modifications are incorporated in the following description of the procedure.

Variable amounts of soil (between 0.5 g and 4.0 g) are taken and the entire sample is ground in a mortar with 4 or 5 changes of sterile water (5 ml. water being used at each change). The time for the first grinding is 5 min and for the subsequent grindings 2 min each. Thus a total of 20–25 ml. of soil-water suspension is obtained.

All the soil particles are poured into the collecting container for the soil-water suspension, because observation of the larger soil particles left behind in the decantation procedure suggested in the original description of the technique<sup>2</sup> revealed the presence of fungal hyphae (a large proportion of which appeared to be free in the water retained by the soil, not directly associated with the larger soil particles).

Molten 1.5 per cent 'Oxoid No. 3' agar is then added to the soil-water suspension to give a known final dilution of the original soil sample (approximately 1 g soil in 50 ml.). The dilution prepared depends on the soil under investigation (in soils with a large amount of mycelium a higher dilution is used) and preliminary experiments are required to ascertain the optimum dilution for the soil under investigation. The final soil-water-agar suspension is maintained at 50°–60° C for the very short period between preparing the final suspension and the preparation of the agar films.

Immediately before preparation of the film the soil-water-agar suspension is thoroughly agitated and allowed to settle for 5–10 sec before small amounts of the suspension are pipetted from approximately 1 cm below the surface, placed on the platform of a haemocytometer slide (depth 0.1 mm). The well of the slide is immediately covered by a coverslip and the enclosed suspension is left to solidify. Care must be taken to ensure that the soil-water-agar suspension does not overflow from the haemocytometer platform as the depth of the film prepared will then exceed 0.1 mm.

Various possible sources of error have been checked. (i) It is conceivable, for example, that despite thorough stirring of the soil-water-agar suspension immediately before pipetting off small samples for the agar film preparation, there was an accumulation of mycelium floating on the surface of the suspension. This would lead to an overestimate of the amount of mycelium, since samples were always taken from just below the surface. A series of agar films was made from samples taken from three levels in a single soil-water-agar suspension (that is, top, middle and bottom). Four slides were made from

Table 1. TEST OF DISPERSION OF MYCELIUM IN THE SOIL-WATER-AGAR SUSPENSION: LENGTH OF MYCELIUM (M/G SOIL) BASED ON OBSERVATIONS OF AGAR FILMS PREPARED FROM 3 DEPTHS IN THE SOIL-WATER-AGAR SUSPENSION

Sampling position	1	2	Slide No. 3	4	5
Top	133.3	126.0	127.0	133.2	129.9
Middle	132.7	136.1	140.1	131.8	135.2
Bottom	141.0	138.3	127.2	139.9	135.6

Table 2. TEST OF PIPETTING PROCEDURE: LENGTH OF MYCELIUM (M/G SOIL) BASED ON OBSERVATION OF AGAR FILMS PREPARED FROM SUSPENSION FROM THREE POSITIONS IN THE PIPETTE

Sampling position in the pipette	1	2	Slide No. 3	4	5
Tip	93.2	99.6	90.1	95.6	94.0
Middle	100.5	96.2	94.0	91.8	95.6
Top	103.6	94.3	96.8	92.0	96.7

samples from each position; 100 observations were made per slide and the amount of mycelium at each depth was estimated (Table 1). There were no marked differences. (ii) The tip of the hand-drawn pipettes used was about 0.5 mm, and the possibility existed that in drawing up the suspension into the pipette there could be an accumulation of mycelium at the tip of the pipette, its narrow entrance acting as a filter. This would cause an overestimate of the amount of mycelium per unit amount of soil because only the first few drops delivered by the pipette were used in the preparation of an agar film. Quantitative assay of the mycelial lengths from preparations made from successive deliveries from the same pipette, however, indicated no filtering effect (Table 2). (iii) Because of the viscosity of the soil-water-agar suspension, the agar films produced could be thicker than 0.1 mm, therefore allowing an overestimate of mycelium lengths. This has been found to occur. To overcome this a small square weight (approximately 5 g) cemented to a coverslip can be placed over the suspension held in the well of the haemocytometer slide.

After the soil-water-agar suspension has solidified on the haemocytometer slide, the slide is immersed in distilled water and the coverslip removed. Surplus agar in the moats of the haemocytometer is cut away with a razor blade and the agar film is floated off with the aid of a fine camel-hair brush on to an ordinary microscope slide and allowed to dry at room temperature (acceleration of the drying process may cause cracking of the agar film). The dried agar film is then stained for 1 h using phenolic aniline blue, washed in 3 or 4 changes of 98 per cent alcohol and mounted in Euparal.

The slides are examined under the microscope ( $\times 200$ ) and lengths of mycelium in each of a number of fields on each slide are measured. The number of fields per slide and the number of slides examined per soil sample is experimentally and statistically determined. Measurement of hyphal lengths is made either by projecting the images of the fields examined, and measuring the hyphal fragments with a tachometer, or by means of a camera lucida drawing of the hyphal fragments in each field, the total amount of hyphae per field being measured by a tachometer. Thus lengths of mycelium in unit weight or volume of soil can be assessed by taking into account the area of the fields observed, the depth of the agar film, the number of fields viewed, the total volume of soil-water-agar suspension observed, and the degree of dilution of the original soil sample.

## ENTOMOLOGY

## New Organ in Stenocephalidae (Hemiptera-Heteroptera)

INVESTIGATIONS have revealed the presence of a pair of hitherto undescribed organs of unknown function in the abdominal cavity of males of the genus *Dicranocephalus* Hahn (*D. agilis* the type species, *D. albipes*, *D. marginicollis*, *D. setulosus* and *D. lateralis* have been examined). These sac-like structures are situated principally in the seventh segment and appear to be formed by a prolongation of the posterior ventral margin of the eighth segment (Figs. 1 and 2) and are about 1 mm long. Distally the sacs are joined to a sclerotized plate from which arise about twenty-five to thirty semi-erect heavily sclerotized and pigmented tubes (Fig. 3), the entire structure being an invagination of the inter-segmental membrane of the eighth segment (Figs. 1 and 2).

The organs were first observed when entire abdomens were cleared (caustic potash, acetic acid and creosote): their surviving this treatment and their anatomical origin suggest the organs are exoskeletal. After clearing, the organs are hyaline and appear to be composed of a large number of plates overlapping rather like the tiles of a roof (Fig. 4), each being enlarged where it is exposed externally. Each plate has transparent spine-like processes scattered about in irregular groups (Fig. 5), the groups of processes increasing in number and density where the organs join the sclerotized plate. The sacs fill with air when they are heated in caustic potash. When the air is expelled by slight pressure it can be forced into the lumen of the sclerotized tubes and trapped there, although it disappears after several hours by diffusion. This suggests that the inter-segmental invagination must extend under the plate as an air-tight flattened sac.

The tubes are directed downwards towards the ventral surface of the abdomen and are of variable length; the longest on the margins, the shortest in the centre of the sclerotized plate. Each tube is densely clothed with semi-erect hairs, the hairs increasing in length and density distally (Fig. 6).

No similar structures have hitherto been described in Heteroptera, but an analogous organ has been found in the S. African pentatomid genus *Boerias* Kirkaldy<sup>1</sup>. In

*Boerias* there is a median sac lying within the ninth segment and opening into the extreme apex of the rectum; the duct is apparently closed by a pair of ligaments. Leston's structure is similar to that described here in being exoskeletal. All other ectodermal abdominal sacs described, for example, the large rectal diverticulum of *Belostomatidae*, are found in both sexes and in belostomatids are defensive in function.

It is possible that the sacs of *Dicranocephalus* collect a secretion from epidermal glands situated at the apices of the spine-like processes, and their function is almost certainly associated with mating.

### Trans-4-oxohex-2-enal in the Odoriferous Secretion of *Sigarafalleni* (Fieb.) (Hemiptera-Heteroptera)

INTEGUMENTARY glands which produce odoriferous substances are of widespread occurrence in the Heteroptera. The glands are not confined to terrestrial forms but are found also in many aquatic species. Paired dorso-abdominal glands are present in the nymphs, but at the time of the adult moult these are replaced by glands in the metathorax which open to the exterior on the ventral surface.

Short-chain aliphatic aldehydes of variable chain length ( $C_6$ – $C_{10}$ ), both saturated and unsaturated, have been found in the secretions of coreids<sup>1,2</sup>, pentatomids<sup>2-5</sup> and the cimicid *Cimex lectularius* L.<sup>5</sup>. In addition to aldehydes the secretions of some pentatomids have been found to contain the paraffins dodecane and tridecane<sup>2,3</sup>. Unidentified constituents include dicarbonyls<sup>2,3</sup> and possibly furans and quinones<sup>6</sup>. *Trans*-hex-2-enyl-acetate has been identified in the secretion of males of the giant waterbug *Lethocerus indicus* (Lepeletier and Serville), and because it is sex-specific is thought possible to function as a sex attractant<sup>7</sup>. This would appear to be unusual, however, for there can be little doubt that the secretions

Fig. 1. Ventral view of abdomen of *D. albipes* (vi.s.; vii.s.; viii.s.; ix.s.) sixth to ninth abdominal segments; (p.s.) paired sacs; (t.m.) inter-segmental membrane; (t.) trichobothria; (s.) spiracles; (s.p.t.) sclerotized plates with tubes; (p.) parameres. Fig. 2. Side-view of eighth and ninth abdominal segments of *D. marginicollis*, parameres removed. Fig. 3. Sclerotized plate with tubes of *D. albipes* (b.p.s.) base of paired sacs; (s.p.) sclerotized plate; (s.t.) sclerotized tubes. Fig. 4. Proximal ventral view of sac of *D. marginicollis*. Fig. 5. Section of sac showing irregular grouping of transparent spine-like processes of *D. marginicollis*. Fig. 6. Tubes on sclerotized plate showing variation in length and density of hairs of *D. albipes*.

are widely used as a defence against predators, at least in the terrestrial Heteroptera<sup>8</sup>.

In members of the aquatic Corixidae the secretory apparatus of the adult comprises a pair of tubular glands and a median sac-like reservoir<sup>9</sup>: the external opening lies between the hind coxae and is provided with a closing mechanism. The secretion appears to be forced out by the elasticity of the distended reservoir and by an increase in body pressure. It passes into a cavity above the metasternal process to be conveyed along a pair of furrows in the cuticle, left and right, as far as a notch on the posterior edge of each mesothoracic epimeron which bears a tuft of slender bristles. The secretion exudes to form a pair of droplets which appear to be brushed off by the hind legs.

We have investigated the composition of the secretion of adults of *Sigara falleni* (Fieb.). The secretion was a pale yellow oil with a pleasant odour reminiscent of 'leaf aldehyde' (hex-2-enal). The main constituent was identified by its chemical and physical properties and by synthesis as *trans*-4-oxohex-2-enal (*trans*-3-propionyl acrylaldehyde), which appears to be new to the chemical literature. A minor constituent (less than 5 per cent) was not identified.

The secretions of male and female *S. falleni* were not distinguishable. Similarly, no difference could be found between the secretions of *S. falleni* and *Corixa dentipes* (Thoms.). It would thus appear that the secretion is neither sex- nor species-specific and may well be characteristic of the Corixidae.

The function of the secretion has not been investigated. There is some evidence to indicate that fish tend to avoid Corixidae<sup>10</sup>, but whether on account of the odoriferous secretion is not known. While the secretion may act as a defence against predators there is the possibility that it also confers some protection against micro-organisms by preventing them from settling on the body surface; some aldehydes have been shown to have both fungicidal and bactericidal properties<sup>6</sup>.

## VIROLOGY

### Virus of Feline Panleucopænia

PROGRESS in understanding the immunological features of feline panleucopænia has, for many years, been impeded due to failure to isolate the causal agent of the disease. That this agent has the properties of a virus has been evident since the original observations of Verge and Christoforoni<sup>1</sup>, but although many viruses have been isolated from sick and healthy cats, none has been shown to be related to the feline panleucopænia syndrome<sup>2</sup>.

In February last year a virus, leopard virus (LV), was isolated in kitten kidney monolayers from the spleen of a leopard which died from a condition simulating feline panleucopænia<sup>3</sup>. The following evidence has since been accumulated that this virus is involved in the feline panleucopænia syndrome.

(1) The transient intranuclear inclusions seen in cells in tissue culture show stages of nuclear changes similar to those seen in gut epithelium cells of naturally affected kittens. Similarly, in organ cultures of cat spleen infected with third tissue culture passage LV, intranuclear inclusions appeared having the same morphology and distribution as those seen in organ cultures infected with extracts of feline panleucopænia tissues supplied by Wellcome Research Laboratories.

(2) Viruses showing the same characteristic transient cytopathic effect as LV have been isolated from four out of five field cases of feline panleucopænia which were diagnosed as such on clinical and histological features. A similar virus was also isolated from tissues supplied by Wellcome Research Laboratories. No such viruses have been isolated from the spleens of healthy cats, or cats dying from conditions other than feline panleucopænia.

(3) The properties of the virus in tissue culture fluids correspond closely to the properties of the virus of feline panleucopænia agent from infected tissues, in size of virus and the failure to infect other hosts *in vitro* and *in vivo*.

(4) The cytopathic effect of LV and the five other isolates is neutralized by high dilutions of hyperimmune feline panleucopænia sera, and similar neutralizing antibodies have been detected in a majority of normal cats and suckling kittens in this area, suggesting that infection with the virus is fairly common.

(5) Kittens showing low level antibodies to LV on being infected with fourth tissue-culture passage of LV developed panleucopænia and depression, similar in all respects to that shown by litter-mates infected with feline panleucopænia tissues.

(6) Kittens recovered from infection with LV resisted challenge with feline panleucopænia tissues, while litter-mates recovered from infection with feline panleucopænia tissues resisted challenge with passaged LV. In both instances control kittens developed typical panleucopænia.

(7) Following infection with feline panleucopænia tissues, kittens showed an antibody rise to LV similar to the antibody rise shown in litter-mates infected with feline panleucopænia tissues.

From the evidence accumulated, to be published in a more detailed form, it would appear that a virus has been isolated which is very closely related to the feline panleucopænia syndrome. It is considered highly probable that this virus is the causal agent of the disease.

## GENETICS

### Isolation of Ploidy Mutants of Ehrlich Ascites Tumour of Mouse

To examine the effect of polyploidy on radiosensitivity in mammalian cells, it is desirable to induce a ploidy mutant from a clone derived from a single cell. Theoretically such a cell clone could be isolated by the tissue culture method developed by Puck *et al.*<sup>1</sup>. The following technique of injecting single cells is applicable also to cells which are difficult to culture *in vitro*.

A hyperdiploid line of Lettré's Ehrlich ascites tumour of mouse (ELD) served as the starting material. Adult as well as new-born mice were used as host animals. The

tumour was transplanted into the adult mice by injecting more than  $10^7$  cells. The new-born mice, which were not more than 48 h old, and which were previously irradiated with 300 r. of X-rays to stop the antigen-antibody reaction against the tumour, were injected intraperitoneally with a single tumour cell. Single cells were isolated from a dilute suspension of cells with the help of a micromanipulator. The cell was sucked from an airtight chamber into a thin capillary tube and was injected into the peritoneal cavity of the mouse with the finely drawn out point of the capillary tube. The dilution medium had the following composition: doubly distilled water 100.00; NaCl 0.95; foetal bovine serum (Microbiol. Assoc., Bethesda), 15.00; neomycin, 0.025; polymyxin, 0.0025. Native tumour ascites was diluted with the dilution medium to 1:125. The complete operation from the withdrawal of the tumour to the injection of single cells into the peritoneal cavity of the new-born mouse was performed in less than 1 h. The chamber, containing the suspension of tumour cells, was made by placing an ultra-violet-sterilized polymethacrylic acid ('Lucite' or 'Perspex') ring between two sterilized coverslips stuck on with a drop of liquid paraffin. A small hole in the ring permitted filling and micromanipulation, and the chamber was filled with a thin injection needle, avoiding air bubbles. The opening in the plexiglass ring was finally sealed with a drop of liquid paraffin. By inserting the capillary tube through this drop into the cell suspension (Fig. 1) it was possible to prevent a direct contact between cell suspension and air during the micromanipulation and thus to avoid drying by evaporation. The free sliding of the ring on the coverslips facilitated the manipulation and guidance of the capillary tube.

Fig. 1. 1 and 2, coverslip; 3, ring made from 'Perspex'; 4, capillary tube; 5, liquid paraffin

A certain number of new-born mice thus injected with a single cell each of the hyperdiploid line ELD developed tumour ascites about 3-4 weeks after injection which could easily be detected visually. All single-cell clones thus produced were analysed cytologically by the Feulgen method. To induce polyploidy by colchicine, two types of diploid clones were selected. 0.5 ml. of 2 per cent colchicine was injected intraperitoneally into the tumour ascites developed 8 days after transplantation of cells from a selected hyperdiploid clone. After about 2.5 h, the ascites was withdrawn, and, after washing, either single cells were isolated immediately and directly injected into new-born mice, or more than  $10^7$  cells were transplanted into adult mice. In this case single cells were isolated only after an intermediate tumour passage. The sub-clones thus produced were examined again cytologically.

Out of about 160 new-born mice, each injected with one single cell of line ELD, 40 single-cell clones were isolated. The chromosome number distribution of the stemline ELD and of the isolated clone ELDD<sub>1</sub> is given in Table 1.

Table 1

Chromosome No./cell	No. of cells		ELDD <sub>1</sub> + colchicine*
	ELD	ELDD <sub>1</sub>	
40	28	5	6
41	42	14	10
42	240	87	43
43	66	33	16
44	60	12	9
45	28	4	7
46	19	1	3
47	15	—	—
48	12	—	1
49	12	—	—
50	10	—	—
51-79	14	—	—
>80	16	5	14

\* Cells examined after one intermediate tumour passage.

In both cases the modal chromosome number was 42. However, the chromosome distribution spectrum of the clone ELDD<sub>1</sub> was narrower than in the stemline ELD. The proportion of hypertetraploid cells in the line ELD and in the clone ELDD<sub>1</sub> was about 3 per cent. After the colchicine treatment of the clone ELDD<sub>1</sub> and examination of the tumour after one intraperitoneal transfer, the proportion of hypertetraploid cells increased to about 14 per cent. From the clone ELDD<sub>1</sub>, treated with colchicine, sub-clones were isolated either with (group I) or without (group II) an intermediate passage and one such clone proved to be a hypertetraploid. Altogether, 20 sub-clones were isolated; 13 belonging to group I and 7 to group II, and 13 were examined in cytological detail. The hypertetraploid clone isolated belonged to group II, that is, the cell was injected immediately after colchicine treatment without any intermediate tumour passage.

Table 2

Chromosome No./cell	ELDT <sub>1</sub> No. of cells
80	—
81	4
82	3
83	16
84	38
85	20
86	12
87	3
88	2
89	—
90	—
>91	12

The chromosome number distribution of this isolated hypertetraploid (ELDT<sub>1</sub>) is given in Table 2. The modal chromosome number, 84, was exactly double that of the parent clone ELDD<sub>1</sub>. The characteristic median chromosome of ELDD<sub>1</sub> was represented twice in ELDT<sub>1</sub>. Thus it may be inferred that the chromosome number 42 of a cell of ELDD<sub>1</sub> was doubled and that certainly only one such cell was injected into a new-born mouse. Such hypertetraploid cells occur in the clone ELDD<sub>1</sub>, immediately after colchicine treatment, with a frequency of about 30 per cent. It thus follows that the isolated sub-clone ELDT<sub>1</sub> is induced by colchicine treatment with a probability ~ 0.9 and does not originate as a spontaneous mutant. Hornsey and Silini<sup>2</sup> and Révész *et al.*<sup>3,4</sup> have compared the relative radiosensitivity of a diploid line with a 'tetraploid' line of Ehrlich ascites tumour. They found that the 'tetraploid' line was more radio-resistant than the diploid line, under anaerobic conditions. Till<sup>5</sup>, on the other hand, failed to find any relationship between the chromosome number and radiosensitivity in lymphosarcoma cells. The hypertetraploid<sup>6</sup> Ehrlich tumour line investigated by us (Bhaskaran and Ditttrich) was found to be extremely radiosensitive. The conclusions drawn from the experiments conducted so far are not conclusive, because one cannot exclude the possibility that the lines compared, apart from ploidygrade, differ from each other genetically. Such a difficulty could be avoided by comparing a tetraploid sub-clone derived from a diploid clone, cultured from a single cell. The relative radiosensitivities of ELDD<sub>1</sub> and ELDT<sub>1</sub> are under investigation.

### Computer Analysis of Concordance of Inherited Characteristics

IN anthropological surveys, investigations of the effects of mutagenic agents, and similar projects, the transmission of hereditary characters is frequently investigated in large populations. Where data are available it is advisable to ascertain whether the children's phenotypes agree with those of their presumptive parents. Lack of agreement indicates that the data were influenced by factors other than family relationships, for example, illegitimacy, errors of labelling, technique or recording, or the effects of mutation. The greater the number in the group, the more likely are the factors producing disagreement to be identified, but the more burdensome becomes the labour of correlation.

A digital computer programme had been evolved to analyse concordance, within families, of two unrelated characters (haptoglobin and transferrin) each determined by two frequently-occurring alleles, and to record variants due to a third allele, for use with data derived from processing of sera obtained in an anthropological survey of New Guinea natives. This programme, however, could not be used with data involving characters determined by more than two alleles, such as blood groups, haemoglobins, etc., so a general programme was evolved to enable the more complex data to be included.

Both programmes were written in the Fortran II autocode<sup>1</sup> for the I.B.M. '1401' computer although other computer languages such as Algol<sup>2</sup> could have been employed. The general programme is described here both because of its novel function and because it uses a digital computer in its algorithmic role to perform repetitive decisions.

An identifying number was allotted to each individual (NI) and to each family (NF). A family was defined as the two parents and their children. If an individual belonged to more than one family because of multiple marriages or because more than two generations were recorded he was allotted a card for each family and these cards differed from one another only in the NF number and in the parental status (NP) which was defined as mother (2), father (1) or child (0). Because each variable inherited (phenotypic) characteristic (M) was assumed to have been determined by the action of only two genes (S and T, derived one from each parent) it was encoded in two columns, defined as NS(M) and NT(M) of an 80-column Hollerith card. The characters expressed by alleles of genes S and T were represented in columns NS(M) and NT(M) respectively by numbers 1-9, a particular number having been assigned to the character expressed by the corresponding allele. An individual was encoded as a homozygote for the expressed allele when a character due to another allele was not observed because subsequent identification of 'misfits' by the computer in the related family allowed recognition of the individual as a possibly heterozygous parent. Each instruction to the computer contained in the programme is termed a

'statement' and may be identified by a reference number<sup>1</sup>. To commence the sequence the computer is instructed to read the first two cards and to index and store the values punched in them. The representation within the computer of all values punched in a card may be termed a 'card image'<sup>3</sup>. In a following statement the computer is instructed to compare the NF numbers of the two cards and, depending on the outcome, to decide which set of instructions it should follow. The general form of such a statement is:

$$\text{If } (M - N) \text{ } 1, 2, 3 \quad (1)$$

which can be translated "if  $M < N$  follow instruction 1; if  $M = 0$  follow instruction 2; and if  $M > N$  follow instruction 3", where M and N are real positive integers. Any two of these instructions may be identical as in the statement:

$$\text{If } (M - N) \text{ } 1, 2, 1 \quad (2)$$

which reduces the choice to one of two alternatives, and any one or two of these instructions may lead to the execution of a preceding instruction and thus establish a repetitive process which is continued until an alternative instruction can be executed or all cards have been read.

The specific form of the instruction to compare the NF numbers of two card images is:

$$\text{If } [NF(I) - NF(N)] \text{ } 1, 2, 3 \quad (3)$$

where I is the last and N the penultimate card image. If the cards are identical [ $NF(I) = NF(N)$ ] the next card is read and examined and so on until  $NF(I)$  exceeds  $NF(N)$  when the card images of the whole family have been stored and when another instruction is selected. The new instruction is to select the parents' card images (condition  $NP(I) \geq 1$ ):

$$\text{If } (NP(I) - 1) \text{ } -, 0, + \quad (4)$$

and to assign to the values of their inherited characteristics the subscripts<sup>1</sup> J and K (or J only if there is but one parent) in the form NS(J,M) and NT(J,M), etc.

The children's card images are also identified by statement (4) (condition  $NP(I) < 1$ ), their genetic characteristics are subscribed NS(L,M) and NT(L,M), etc., and comparison is then made with the characteristics first of one parent and then of the other:

$$\text{If } [NS(J,M) - NS(L,M)] \text{ } -, 0, + \quad (5)$$

As the computer directly compares the children's characters with those of the parents, an allelic array larger than 2 can be processed without altering the programme, and as the inherited characters are sequentially examined their number can be indefinitely extended by postponing only the last instruction, which is that the last card image stored (I), corresponding to the first card of the next family, should be indexed as the first, and that the reading for the following cards should commence.

If the genetic polymorphism of the characteristic is sufficiently large the programme can also be expanded to include the sequence for analysing a family consisting only of siblings. This sequence can be executed provided that there are at least three siblings, when the presence of two allelic homozygotes precludes there being more than two allelic genes in the sibship, when the presence of one homozygote allows no more than three alleles in the sibship, and when the absence of homozygotes allows no more than four alleles to be found (parents  $ST \times ST$ ,  $S^1T \times S^2T$  and  $S^1T^1 \times S^2T^2$  respectively). The decision as to which alleles 'belong' and which do not can only be made on statistical and not logical grounds, and the computer is therefore instructed to print the values of the whole family after determining whether the family obeys or does not obey the conditions of sibship.

I can supply copies of both programmes to which reference has been made. I thank Dr. C. C. Curtain of the Baker Medical Research Institute, Melbourne, for

advice. The work was done during my tenure of a research fellowship from Alfred Hospital, Melbourne.

## STATISTICS

### All-or-none Traits and the Sensitivity of Experiments

THE choice of the strain of laboratory animal has been examined by Chai<sup>1</sup>, by Biggers, McLaren and Michie<sup>2</sup>, and by Becker<sup>3</sup>. Much of the discussion in these papers involved the choice of mice of inbred strains or those of the  $F_1$  generation for bioassay. In addition, Becker and Berg<sup>4-6</sup> have reported tests which were designed to determine which sex and strain of chickens produced the most sensitive nutritional experiments.

Many of the examples have used measurements of continuous or quantitative traits such as body-weights, observations on cell heights and mouse reflex times. The sensitivity of a specific experiment involving a quantitative trait can be measured by the ' $F$  value'. It represents the ratio of the among-treatments mean square to the within-treatments mean square, or that of the regression mean square to the mean square of deviations from linear regression in the analysis of variance. The theory and application of the use of the  $F$  value as an indication of the sensitivity of experiments have been set forth by Schumann and Bradley<sup>7,8</sup>.

An opportunity to investigate some aspects of the choice of animals and the sensitivity of experiments when an all-or-none trait was used was provided when four selection lines of White Leghorn chickens developed by Becker and Bearse<sup>9</sup> were each placed on two nutritional treatments in each of two years. The trait was the presence or absence of a blood spot in the egg as determined by observations of the broken-out egg within 72 h of oviposition. The treatments employed in this investigation were a ration adequate for egg production but lacking sufficient vitamin A, and one that was fortified with this vitamin. Diets below optimum requirements for egg production in vitamin A were shown to raise the blood spot percentage<sup>10</sup>.

Lines 1 and 2 had been selected for a low incidence of blood spots and Lines 3 and 4 for a high incidence. In both years (Exps. 1 and 2) hens' records were randomly removed so that there were equal numbers of hens within each sub-class in each analysis.

In Exp. 1,  $n = 68$  per sub-class, and the incidence of blood spots was determined for all eggs laid by each hen in a 10-day period. In Exp. 2,  $n = 69$  per sub-class, and eggs laid during a 20-day period were broken open and examined. The incidence of blood spots was calculated for each hen.

A one-way layout of the analysis of variance was computed for each of the lines in each of the two years and the  $F$  value (ratio of mean square, between dietary treatments, to mean square among hens within diets) was calculated. The arc sine transformation resulted in only slight changes in the  $F$  values. Therefore, data reported herein refer to the actual percentages only.

The estimates of the overall mean, the response of a line to the dietary changes (expressed as the difference between diets), the variance component attributable to the fact that diets were different, the error term and the  $F$  value of the one-way layout analysis for both experiments are given in Table 1. The results, in general,

Table 1. A COMPARISON OF FOUR BLOOD SPOT SELECTION LINES USED IN EXPERIMENTS DESIGNED TO DETERMINE DIFFERENCES IN BLOOD SPOT INCIDENCE FED DIETS EITHER ADEQUATE OR INADEQUATE IN VITAMIN A (VARIANCE  $\times 10^3$ )

Line	Blood spot incidence	Average over both diets $\bar{x}$ %	Adequate diet— inadequate diet %	Variance component	Error term	$F$ value
Experiment 1						
1	Low	11.4	7.6	280	2,824	7.7*
2	Low	17.5	11.5	584	4,980	9.0*
3	High	24.0	16.6	1,316	4,558	20.6†
4	High	39.8	28.9	3,651	8,141	30.4†
Experiment 2						
1	Low	12.0	7.7	260	2,142	9.4*
2	Low	12.7	5.2	64	4,118	2.1
3	High	23.9	13.5	858	4,367	14.6†
4	High	27.8	16.0	1,223	3,969	22.3†

\* Significant at the 1 per cent level.

† Significant at the 0.1 per cent level.

indicate that as the overall mean increased, the error term, response to diet, variance component and  $F$  value also increased.

Thus, the experiments involving an all-or-none trait were more sensitive, as determined by the  $F$  value, when the lines utilized had a genotypically higher incidence than when low incidence lines were used. In these experiments the data indicate that greater reliance could be placed on the results as the incidence of the all-or-none trait approached 40 per cent.

Table 2. EXPERIMENTS DESIGNED TO DETERMINE DIFFERENCES AMONG BLOOD SPOT SELECTION LINES ON DIETS ADEQUATE AND INADEQUATE IN VITAMIN A (VARIANCE  $\times 10^3$ )

Diet	Average $\bar{x}$ %	Variance component	Error term	$F$ value
Experiment 1				
Inadequate	31.0	260	673	27.3*
Adequate	15.3	594	3,515	12.5*
Experiment 2				
Inadequate	24.4	1,030	4,007	18.7**
Adequate	13.8	261	3,291	6.5*

\* Significant at the 0.1 per cent level.

It was also possible to analyse the data to determine the effect of the environment on the sensitivity of experiments when four lines were assumed to be the treatments. In Table 2 the overall mean, the variance component attributable to the fact that the lines were different, the error term and the  $F$  value (ratio of mean square among lines and among individuals within lines) are given. The experiments on the inadequate diet, which raised the incidence, had larger  $F$  values than the experiments determining differences among lines on the adequate diet.

It seems, therefore, that raising the incidence of an all-or-none trait, either by changing the environment when determining genotypic differences or by using genotypically high-level strains when ascertaining environmental differences, resulted in more sensitive experiments.

Whether or not the sensitivity of the experiments would react in the same manner for other all-or-none traits, other environments and other genotypes, would have to be determined by further experimentation.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, January 4

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. R. Knight and Mr. K. Hambleton: "The Present State of Gallium Arsenide Technology".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—Geographical Films.

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. B. E. Moody: "Recent Developments in Container Glass".

## Tuesday, January 5

BRITISH INTERPLANETARY SOCIETY (in the Large Physics Theatre, University College, Gower Street, London, W.C.1), from 10 a.m. to 4.30 p.m.—Symposium on "The Engineering of Scientific Satellites".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Prof. S. Tolansky, F.R.S.: "The Curiosities of Sound" (Dr. Mann Juvenile Lecture).

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. Robert Mathieson and Mr. John Stebbings: "Design of a Modern Hydraulics Laboratory for Teaching and Research".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (joint meeting with the Science and General Division, at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. J. C. West, Dr. B. V. Jayawant and Mr. G. Williams: "Dynamic Performance of Induction Motors in Control Systems".

INSTITUTION OF MECHANICAL ENGINEERS, STEAM PLANT GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Water-Level Indicators for Pressure Vessels".

## Wednesday, January 6

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 3 p.m.—Meeting on "The Design of Ship's Bridges".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. P. J. Lawrenson and Mr. L. A. Agu: "Theory and Performance of Polyphase Reluctance Machines".

INSTITUTION OF MECHANICAL ENGINEERS, THERMODYNAMICS AND FLUID MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Fluid Dynamic Model Tests as a Basis for Engineering Design".

## Thursday, January 7

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (at the Imperial College of Science and Technology, London, S.W.7), at 3 p.m.—Symposium on "Paint versus Corrosion".

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 3 p.m.—Mr. R. Stanton Jones: "Ground Effect Vehicles" (Young People's Lecture).

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Is the Civil Engineer's Responsibility being Subordinated to Administration?" introduced by Mr. E. C. Beck and Mr. Oliver Dawson.

INSTITUTION OF MECHANICAL ENGINEERS, PROCESS ENGINEERING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Electrostatic Hazards in Factories".

## Friday, January 8

BRITISH MYCOLOGICAL SOCIETY (in the Department of Mechanical Engineering, City and Guilds College, Exhibition Road, London, S.W.7), at 10.45 a.m.—General Papers.

## Monday, January 11

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. S. Wilkie: "Modes of Causality in the Language of Biologists".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. J. Swafield: "Speech Compression".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Sir Vivian Fuchs: "Recent British Exploration in Antarctica".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

RESEARCH ASSISTANT (with a good honours degree) IN THE DEPARTMENT OF AGRICULTURE (Crop Husbandry) to assist with experimental work on the improvement of grassland—The Registrar, University College of Wales, Aberystwyth (January 9).

RESEARCH BIOCHEMIST (with at least a good second-class honours degree) to assist Dr. R. M. C. Dawson in lipid metabolism studies—The Secretary, Institute of Animal Physiology, A.R.C., Babraham, Cambridge (January 9).

ASSISTANT LECTURER (with an honours degree in pharmaceutical chemistry or equivalent, and preferably some experience in industrial research or medicinal chemistry) IN PHARMACY—The Registrar, The University, Manchester, 13 (January 11).

POST-DOCTORAL RESEARCH FELLOW IN THE APPLIED NUCLEAR SCIENCE GROUP, DEPARTMENT OF PHYSICS, for work concerned with the problems of dental caries under the terms of a Medical Research Council award—The Administrative Officer, Department of Physics, The University of Birmingham, Birmingham, 15 (January 11).

CHAIR IN ORGANIC CHEMISTRY, in an integrated Department of Chemistry; CHAIR IN THE DEPARTMENT OF MATHEMATICS; and CHAIR IN THE DEPARTMENT OF PHYSICS—The Secretary, Battersea College of Technology, Battersea Park Road, London, S.W.11 (January 12).

GRADUATE CARTOGRAPHER (person who has included geography in their degree, with experience in the compilation and drawing of maps for publication) IN THE DEPARTMENT OF GEOGRAPHY—The Secretary, The University, Aberdeen (January 15).

LECTURER IN BACTERIOLOGY at the Western Infirmary—The Secretary of University Court, The University, Glasgow (January 16).

UNIVERSITY LECTURER IN THE STATISTICAL LABORATORY IN THE DEPARTMENT OF PURE MATHEMATICS AND MATHEMATICAL STATISTICS, University of Cambridge—The Secretary of the Appointments Committee, Faculty of Mathematics, Arts School, Bene't Street, Cambridge (January 16).

LECTURER IN ANTHROPOLOGY—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (January 18).

CHAIR OF EDUCATION at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 22).

LECTURER OR SENIOR LECTURER IN CLINICAL PATHOLOGY IN THE DEPARTMENT OF ANIMAL HEALTH, in the Faculty of Veterinary Science, Massey University of Manawatu, Palmerston North, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1, or the Registrar of the University (New Zealand and London, January 22).

SENIOR LECTURER OR LECTURER IN VETERINARY ANATOMY; and a SENIOR LECTURER OR LECTURER IN MICRO-ANATOMY IN THE DEPARTMENT OF VETERINARY BIOLOGY, Massey University of Manawatu, Palmerston North, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1, or the Registrar of the University (New Zealand and London, January 22).

PRINCIPAL (with a degree or honours degree in agriculture, experience of tropical agriculture, administrative ability, and preferably teaching experience) of the College of Agriculture (University of Malaya)—The Secretary, Council of the College of Agriculture, P.O. Box 203, Sungai Besi, Selangor, or The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Malaya and London, January 23).

LECTURER OR SENIOR LECTURER IN MORBID ANATOMY IN THE DEPARTMENT OF PATHOLOGY, University of the West Indies, Kingston, Jamaica—The Secretary, Senate Committee on Higher Education Overseas, University of London, Senate House, London, W.C.1 (January 25).

READER IN PURE MATHEMATICS at Queen Elizabeth College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 25).

ASSISTANT LECTURER IN GEOLOGY—The Registrar, Room (X), The University, Hull (January 26).

ASSISTANT LECTURER IN PURE MATHEMATICS—The Registrar, Room (X), The University, Hull (January 28).

SENIOR LECTURER IN THEORETICAL PHYSICS; LECTURERS OR ASSISTANT LECTURERS IN THEORETICAL OR EXPERIMENTAL PHYSICS; and a DEMONSTRATOR IN THE DEPARTMENT OF PHYSICS—The Registrar, Room (X), The University, Hull (January 28).

ASSISTANT LECTURER OR LECTURER (or, in special cases, Senior Lecturer) IN ELECTRICAL ENGINEERING in the School of Applied Sciences—The Assistant Registrar (Establishment), University of Sussex, Stanner House, Stanner, Brighton, Sussex (January 29).

LECTURER (with a good honours degree in geography, and either a higher degree or actively engaged in research leading to a higher degree) IN GEOGRAPHY, at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (January 29).

READER, SENIOR LECTURER and a LECTURER IN MATHEMATICS at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (January 29).

LECTURER/ASSISTANT LECTURER (with a higher degree in biochemistry, some teaching and research experience, and preferably a special interest in physical biochemistry or enzyme biochemistry) IN THE DEPARTMENT OF BIOCHEMISTRY, University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, January 30).

LECTURER OR ASSISTANT LECTURER IN INORGANIC CHEMISTRY; and a LECTURER OR ASSISTANT LECTURER IN PHYSICAL CHEMISTRY—The Secretary, The University, Aberdeen (January 30).

SUB-LIBRARIAN at the University of Ife, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (January 30).

ASSISTANT LECTURER IN BIOCHEMISTRY—The Registrar, Room (X), The University, Hull (January 31).

HEAD OF THE BACTERIOLOGY DEPARTMENT—The Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh (January 31).

CHAIR IN AND HEADSHIP OF THE DEPARTMENT OF ELECTRICAL AND CONTROL ENGINEERING; CHAIR IN AND HEADSHIP OF THE DEPARTMENT OF MECHANICAL ENGINEERING; and CHAIR IN THE DEPARTMENT OF METALLURGY AND MATERIALS TECHNOLOGY—The Secretary, Battersea College of Technology, Battersea Park Road, London, S.W.11 (February 1).

LECTURER IN PSYCHOLOGY IN THE DEPARTMENT OF EDUCATION—The Registrar, The University, Hull (February 3).

LECTURER (graduate in medicine with experience or special interest in pharmacology) IN PHYSIOLOGY (Pharmacology) at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (February 5).

CYTOTOLOGIST (with a first- or good second-class honours degree in biology or a medical qualification and preferably experience in human or mammalian cytogenetics)—The Director, Population Genetics Research Unit, M.R.C., Old Road, Headington, Oxford (February 15).

HAZEL CLIFFORD POSTGRADUATE STUDENT for research in medicine or on a scientific topic concerned with the advancement of medical knowledge—The Secretary to the Scholarships Committee, University of London, Senate House, London, W.C.1 (February 15).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS (preferably with the degree of Ph.D. or with equivalent research experience) IN BIOCHEMISTRY, CHEMISTRY, ENGINEERING, PHARMACOLOGY, PHYSICS OR CHEMICAL ENGINEERING—The Secretary, The University, Edinburgh (February 15).

NEMATOLOGIST (with a degree in the biological sciences with experience in the identification of plant parasitic nematodes and an interest in taxonomy) at the Commonwealth Bureau of Helminthology, St. Albans, Herts—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (February 15).

ANIMAL HOUSE TECHNICIAN (man or woman with suitable experience and qualifications) to take charge of the Animal House—The Professor of Zoology, The University, Hull.

BIOCHEMIST (with previous experience) for research in hormonal metabolism—Dr. B. H. Billing, Medical Unit, Royal Free Hospital, London, W.C.1.  
CHAIR OF PHYSIOLOGY—The Registrar and Secretary, The University, Bristol.

ENTOMOLOGIST (Tsetse) (with an honours degree in natural science, entomology or zoology) in Zambia (Northern Rhodesia), to plan and assess tsetse control measures involving surveys of fly incidence and its relation to local ecological factors, to determine the most suitable methods of control, and to supervise tsetse control staff—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 217/132/01.

LECTURERS AND ASSISTANT LECTURERS IN THE DEPARTMENT OF PHYSICS—The Registrar, The University, Manchester, 13.

MATHEMATICIANS (specialized in any branch of mathematics and preferably with the degree of Ph.D.)—Head of the Department of Mathematics, Dalhousie University, Halifax, Nova Scotia, Canada.

PHYSICAL CHEMIST OR CHEMICAL ENGINEER (graduate under 30) for research in wool dyeing processes—Wool Industries Research Association, Torridon, Headingley Lane, Leeds, 6.

POST-DOCTORAL FELLOWS IN THE DEPARTMENT OF CHEMISTRY, to work in the field of gas kinetics using flash photolysis and shock wave techniques—Prof. G. Burns, Department of Chemistry, University of Toronto, Toronto 5, Ontario, Canada.

PROFESSOR (preferably with a Ph.D. and some industrial experience) OF MECHANICAL ENGINEERING to teach engineering design and to conduct research in stress analysis or related fields—Head of the Department of Mechanical Engineering, University of Windsor, Windsor, Ontario, Canada.

RESEARCH ASSISTANT (with a degree or diploma in chemical engineering) IN THE CHEMICAL ENGINEERING SECTION OF THE DEPARTMENT OF CHEMISTRY AND CHEMICAL TECHNOLOGY—The Secretary, Borough Polytechnic, Borough Road, London, S.E.1.

RESEARCH ASSISTANT (graduate with training in bacteriology) IN THE DEPARTMENTS OF MEDICINE AND MICROBIOLOGY—Dr. N. Crowley, Microbiology Department, Royal Free Hospital, Gray's Inn Road, London, W.C.1.

RESEARCH BIOCHEMIST (young, well qualified biochemist with a Ph.D. degree and an interest in protein chemistry and enzymology)—Dr. P. J. Mulrow, Yale University Department of Medicine, 333 Cedar Street, New Haven, Conn., U.S.A.

RESEARCH LABORATORY TECHNICIAN (preferably with experience in electronics or optics) to assist in a laser project—The Secretary, Royal Holloway College, Englefield Green, Surrey.

SENIOR GRADE BIOCHEMIST to work under the Chemical Pathologist in a well equipped laboratory—The Assistant Secretary, University College Hospital, Gower Street, London, W.C.1.

SENIOR TECHNICIAN to assist with the development and construction of research equipment—The Secretary, Royal Holloway College, Englefield Green, Surrey.

TECHNICIAN OR JUNIOR TECHNICIAN (preferably with some experience in histology) IN THE DEPARTMENT OF ANIMAL HUSBANDRY at the Royal Veterinary College's field station in Hertfordshire—The Assistant Secretary, Royal Veterinary College, Boltons Park, Hawkshead Lane, Potters Bar, Middlesex.

# UNICAM SP.800

spectrophotometer for routine  
U.V. analysis and complete  
**automation**

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible Spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as *the* outstanding U.V. spectrophotometer. Now, in addition, Unicam offer a set of automation accessories which provide facilities for:

- AUTOMATIC** interchange of up to 4 sample and 4 reference cells
- AUTOMATIC** re-cycling over any preselected wavelength range
- AUTOMATIC** recordings at predetermined time intervals.

*Please send for descriptive brochure*

*Save operator time, increase speed and efficiency with Unicam automation for:*

**ENZYME REACTION RATES**  
**LIQUID COLUMN CHROMATOGRAPHY**  
**ALL ROUTINE ULTRAVIOLET AND  
VISIBLE SPECTROSCOPY**

## Gas Chromatograph Test Set & Reference Signal Source

enables the Chemist or Instrument Engineer to check quickly the operation and performance of his complete Gas Chromatograph equipment. If the equipment is not operating correctly, it will quickly localise the faulty section. No electrical knowledge is necessary to use this Test Set, which is suitable for Flame Ionisation, Thermistor type and Katharometer Gas Chromatographs.

Please write for details now:-

## LAND USE AND RECLAMATION

FOLLOWING on Lord Molson's reference in the House of Lords on November 10 to the memorandum on the preservation of amenities (both within and without the national parks) which was being sent to the Government by the Council for the Preservation of Rural England, the question of electricity pylons in areas of natural beauty was raised in the House of Lords on November 17 by Lord Egremont, who was strongly supported by the Marquess of Salisbury, the Earl of Bessborough, the Earl of Dudley, Lord Chorley, Viscount Mersey and Lord Somers. Lord Egremont was particularly concerned about the position of a small area of outstanding beauty in West Sussex and challenged the commonly accepted figures for the cost of underground cables. Lord Salisbury also questioned these figures as the justification for pylons, while the Earl of Bessborough strongly urged the need for further research, and the Earl of Dudley directed attention to the lack of progress in insulating materials used for this purpose. Lord Chorley quoted a decision of the previous Minister against overhead lines from Derbyshire across South Yorkshire, and Viscount Mersey directed attention to costs of pylons which were often disregarded.

Lord Stonham, who replied for the Government, although promising that the Minister of Power would study the whole debate and note what had been said, gave little positive reassurance. He did not consider that decisions were taken without regard to amenity, and gave a figure of £54,000 per mile for heavy duty 400 kV overhead lines compared with £1,182,000 a mile underground. Moreover, he pointed out that even with underground lines considerable disturbance would be caused by the trenches and drums of cables, and heat-exchanger units would be required every few miles. A good deal of money had already been spent on research, but Lord Stonham did not meet the point that the Ministry of Power—and other departments—appears to be allowed to judge in its own cause.

This position is not new although the question of pylons or underground cables has been the subject of steady protest over the past twenty years. What is new is that while the Minister of Power, like those Ministers for Defence, Transport and Agriculture, is a member of the Cabinet, the Minister for Land and Natural Resources is not, and it is to him and not to the Minister of Housing and Local Government that the National Parks Commission is now responsible. Thus the Commission is now responsible to a Minister who is not of Cabinet rank, whereas the major threats to amenity, so far as Government is concerned, arise from departments the Ministers of which enjoy that status.

That position is disturbing and possibly the more so in that it is the reverse of what might have been expected. In view of the importance which has been attached by the Government itself to the use of land, one would have expected to find that any Minister concerned with that sphere would be in the Cabinet with status equal to—if

not greater than—that of Ministers from whom emanate competing and conflicting claims on that resource. Neither in the Machinery of Government Bill, nor in the debate when the Bill received its second reading in the House of Commons on November 19, was any attention directed to the scope or functions of the Ministry for Natural Resources.

The dangers of this situation are clear enough even in such a pamphlet as *The Right to Roam*\*, recently issued by the Ramblers' Association. Moreover, a study of industrial dereliction and how it may be redeemed, recently published by the Civic Trust†, makes nonsense of the whole structure. It is indefensible to anyone who is concerned with the wise use of land or other natural resources, let alone to those who value in the least degree Britain's heritage of natural beauty or her flora or fauna. The Ramblers' Association merely presents a reasonable survey of some of the pressing problems arising in regard to amenity, particularly in the national parks, including water supply, afforestation, Armed Service training areas, and transport. The Civic Trust, in publishing this survey, displays frankly a responsibility that lies fairly and squarely on the Government and which has implications which, if disregarded, would make part of the Government's programme hypocritical.

By and large, the proposals of the Ramblers' Association cover ground which is traversed by recommendations from the National Parks Commission itself and the Council for the Preservation of Rural England. The Association urges direct finance of the Commission by the Exchequer, including grants of 75 per cent for administrative costs, and removal of any restrictions which prevent the Park Planning Authorities undertaking work which could be done by other authorities under other Acts. All alternatives to reservoirs should be explored before any damage is done to the parks, and the Park Planning Boards should have control over the planting of trees, as well as an effective voice in road policy in their areas. There are other sensible suggestions about road policy appropriate in a national park, about 'areas of outstanding beauty', and a plea is made for early legislation embodying the basic recommendations of the Royal Commission on Common Land.

One of the most significant comments in this pamphlet is the observation that "perhaps the greatest failure of town and country planning is seen in the widespread changes in the character of rural landscapes brought about by isolated developments which contradict the existing and dominant colours, textures, topographical form and scale of the components of the landscape". The Association does not conceal its belief that the discontinuance of the title "Ministry of Town and Country Planning" for the Ministry set up in 1943 represents something more than a greater emphasis on housing.

\* The Ramblers' Association. *The Right to Roam: The Rambler and the Countryside*. Pp. 32. (London: The Ramblers' Association, 1964.) 2s.  
† Civic Trust. *Derelict Land: a Study of Industrial Dereliction and How it may be Redeemed*. Pp. 72. (London: Civic Trust, 1964.) 7s. 6d.

The Association is studiously moderate when it urges that the Ministry of Housing and Local Government's primary duty should be to ensure that in all developments full attention is directed to the maintenance of the existing excellence of Britain's landscape, and that industrial processes should be selected, or developed if not available, which will not disturb the beauty of the countryside. Even then there were grounds for suggesting that what was required was not the restoration of its original title to the present Ministry but the appointment of a real Minister of Town and Country Planning who would be overlord of those of agriculture, transport, housing and local government and perhaps power. Certainly, the protest might well have been much more vigorous had it been foreseen that on the contrary the responsibilities for the National Parks Commission, the Nature Conservancy, the Forestry Commission and Commons Land, as well as for water conservation, would be transferred to a Minister outside the Cabinet, while the Ministers responsible for the conflicting and major unco-ordinated demands on land would remain independent and in the Cabinet.

The gist of the problem is expressed in the first two chapters of the Civic Trust's study, and is admirably brought out in the later chapters, which review such special problems of after-treatment as the establishment of grass and afforestation, before dealing with the main industries concerned—coal in Lancashire; ironstone in Northamptonshire; sand and gravel in Hertfordshire; brick clay in Bedfordshire; limestone in Derbyshire; china clay and tin in Cornwall. Other problems are presented by the disposal of town waste and pulverized fuel ash. These sections are contributed by county planning officers with personal experience of the work. The bibliography, which attests the extent to which the problem has already received attention, bears silent witness to the most conspicuous omission—effective control and co-ordination at the top.

The study is not concerned simply with the 150,000 acres and more which lie derelict in England and Wales alone. That is the legacy of past neglect. Some 36,000 acres of this lies in urban areas where undeveloped land is scarce and expensive; about 24,000 acres of it consists of spoil heaps, abandoned buildings and miscellaneous dereliction and should be reclaimed for urban development as fast as the demand allows, instead of prematurely urbanizing what is left of the open country in the neighbourhood. In the meantime, much of this waste land could be made inoffensive to the eye, and attractive to developers, by restoration so far as possible, to agricultural use. Another 12,000 acres of tipping holes is likely to be needed in due course for town wastes, and it is conceivable that thereafter it could be economically developed as sites for housing or playing fields. Such areas should be kept in reserve for refuse disposal, which might otherwise spread over virgin farm land. The remaining 114,000 acres is in less populous areas where there is no foreseeable prospect of large-scale development, and it is these that could be redeemed by regrading and grassing, or afforestation, so as to merge into the surrounding countryside.

Beyond this, however, there is an annual net addition to Britain's derelict acreage. Of some 12,000 acres a year now being taken for mineral working and tipping-spoil and waste, about 8,500 are later restored to farming use by the operators in compliance with conditions attached to their planning consent. Thus there is a further 3,500 acres a year which requires to be harmoniously

blended back into the landscape while the process of extraction proceeds. The rate of present-day dereliction could be reduced somewhat if more were known about the distribution and industrial usefulness of workable deposits, and if more care were taken to co-ordinate the activities of the various agencies responsible for digging holes and the disposal of wastes. However, there is only limited scope for further abatement of the spread of dereliction by the exercise of planning control over individual mineral undertakings.

Here the study stresses the great and growing contribution which minerals make to the national wealth. They must be worked where they are found, and worked efficiently and economically. The importance of the work of the Geological Survey and of ensuring that it is adequately supported could not be better underlined; while this is now to be the responsibility of the National Environment Research Council under the Ministry of Education and Science, and not, as seems more logical, under the Ministry of Land and Natural Resources, some doubt may well be entertained as to whether the consultations which the Secretary of State for Education and Science promised on November 26 are likely to be anywhere near sufficient.

Land reclamation schemes vary widely in cost, but present experience suggests that if all the 36,000 acres in urban areas were brought back into some sort of use as soon as possible instead of waiting for the time when it was economically ripe for urban development, the gross outlay would average about £700 per acre. Assuming that the market value of the reclaimed land continued to average about £220 an acre, the net cost would be about £480 an acre. On these figures a total of £11.5 million is reached, to which temporary treatment of tipping holes reserved for refuse disposal might add £250,000. Treatment of the remaining 114,000 acres by afforestation or permanent grassing is estimated to cost on average about £55 per acre or £6.25 million in all. A comprehensive 20-year programme for renewing by one means or another all land left derelict by past industrial activities would thus involve an annual outlay of nearly £900,000, or about £1 million if land left derelict by present-day mineral working were included. This figure, moreover, would diminish if the cost of alternative sites on undeveloped land continued to rise, as is probable, and takes no account of the value to the national economy of the farmland saved from premature or unnecessary development.

This figure cannot be regarded as an excessive price to pay for the social and aesthetic benefits that would accrue from the renewal of all derelict land. It should rather be regarded as an essential and inescapable part of the price to be paid for the unavoidable and continuing creation of new eyesores, and should be one of the first responsibilities of any genuine Ministry of Land and Natural Resources. Furthermore, as the Civic Trust reminds us, in the past fifteen years potentialities of landscaping have been transformed by technical revolutions in the mechanisms of shifting waste materials, trees and soils, and especially in the science of soil-making. It is not easy to point to a field where technological advances have more fundamentally transformed the possibilities for improving our environment—or perhaps where their significance has so far been so little appreciated.

This neglect is challenged by this study, which insists that ugliness has an economic as well as a social cost. It is clear enough that to-day it is sheer hypocrisy to

talk of land policy and utilization or of the conservation of natural resources and neglect to deal with this problem of derelict land. Not merely is the cost of reclamation comparatively light; it can yield appreciable economic as well as social returns, while, to say the least, it is imprudent to place no value on amenity.

What is so far completely lacking is any evidence that the Government appreciates what is involved. So far, the present Government has not given any indication that it has any more real concern than its immediate predecessors had for the preservation of amenity or the conservation of natural resources. In a written statement on November 26, the Prime Minister said that the Minister of Land and Natural Planning will be generally responsible for the availability of natural resources to meet the needs of the community and it will be for him to consider the use made of natural resources, the development of new resources, and the better use of those natural resources which are being inadequately used at present. Land is the most important and urgent problem, and the new Minister will be responsible for the establishment of the Land Commission as soon as possible and for future policies relating to the availability of land. Overall responsibility for the national and regional development plans rests with the Secretary of State for Economic Affairs, although the Minister of Land and Natural Resources will participate in their formulation. Transferred to him also will be the functions of the Minister of Housing and Local Government in relation to the National Parks Commission, those of the Minister of Agriculture for the Forestry Commission and for Commons Land, and he will also have responsibilities for the conservation and supply of water (however, the precise allocation of statutory responsibilities for water is to be the subject of a detailed statement later).

It will be noted first that the Nature Conservancy, along with the Geological Survey and Museums and the Hydrology Research Unit, now falls under the Natural Environment Research Council, which is the responsibility of the Ministry of Education and Science. This would appear to place research activities in this sphere on the same basis as research activities in science, medicine and agriculture, though not technology, and at least it remains the responsibility of a Cabinet Minister. Nevertheless, there are strong grounds for holding that a Ministry of Land and Natural Resources should be adequately equipped to pursue its own investigations if not research—reasons at least as compelling as those which have led to the Road Research Laboratory, in the face of the view of its own Board and of some other informed opinion, being transferred to the Ministry of Transport.

The most disturbing aspect, however, is the invidious position in which the Minister of Land and Natural Resources is now placed in relation to those of Transport, of Power, of Housing and Local Government, of Defence, of Agriculture, and of Trade. With no seat in the Cabinet he does not appear to possess the resources for independent enquiry and there is no indication that he possesses the powers to compel the Cabinet Ministers who have conflicting claims on the use of land and other natural resources to consider alternatives before irreparable damage is done. There is not a reference in the Prime Minister's statement to the question of derelict land, for example, nor to this vital co-ordinating and, in the ultimate resort, overruling function which any Minister of Land and Natural Resources must possess if he is to be effective.

## BIOCHEMISTRY OF SPERMATOZOA AND SEMINAL PLASMA

The Biochemistry of Semen and of the Male Reproductive Tract

By Dr. Thaddeus Mann. Pp. xxiii+493+19 plates. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1964.) 105s. net.

MANN'S *Biochemistry of Semen*, published in 1954, was an outstanding synthesis of the information which then existed about the biochemistry of spermatozoa and of their medium, seminal plasma. It contained about 62,000 words and 990 references. The new edition, published in the autumn of 1964, is nearly three times as long and contains twice as many references. It, too, is an outstanding contribution to the subject; but it differs from its predecessor in that it also contains an expanded account of the role of the male sex hormones—testosterone, androstenedione and other steroids—in the production of semen.

The book starts with a general account of semen, that is, spermatozoa and seminal plasma, including one very useful table of the published proceedings of recent congresses devoted to the physiology and biochemistry of spermatozoa. Chapter 2 is concerned with the morphology of spermatozoa (including a superb electron micrograph, by Prof. D. W. Fawcett, of a bat spermatozoon), capacitation, the acrosomal reaction and a somewhat brief account of male- and female-producing spermatozoa. The third chapter describes the male accessory organs and their secretion, seminal plasma. It contains useful photographs and diagrams of the male reproductive tracts of some animals; but further examples could have been included with some advantage.

In Chapter 4 the chemical and physical properties of semen from different species are described. This is an important reference chapter. The fifth chapter is concerned with the enzyme adenosinetriphosphatase, the cytochromes, hyaluronidase and the glycosidases within spermatozoa; the sixth and seventh with sperm proteins and the composition of seminal plasma including the enzymes vesiculase, coagulase, the phosphatases, 5-nucleotidase and amino-peptidase. There is also a valuable discussion of sialic acid in seminal plasma.

Chapters 8, 9 and 10 contain accounts of the important substances spermine, ergothioneine, creatine, serotonin, plasmalogen, prostaglandin, fructose, sorbitol, inositol and citric acid in seminal plasma. The metabolism of spermatozoa, including fructolysis and lipid metabolism, is described in Chapter 11, which also contains an account of sperm energetics.

The influence of hormones, nutrition and other environmental factors on the male reproductive tract and semen *in vivo* is the subject of Chapter 12, while Chapter 13 contains a description of the effects on spermatozoa of variations in the external environment. Chapter 14 deals with sperm antigens and antibodies, sperm-egg interacting substances, chemotaxis and thigmotaxis. Chapter 15 has an applied flavour and contains an account of spermicidal substances.

It would be easy for a reviewer, according to his own preferences and interests, to say that Mann pays too much attention to certain subjects and not enough to others, for example the male sex hormones. But this is a matter of taste and inclination; and it is certain that no readable book in 1964 can satisfy all the specialists likely to read it. In general, Mann has struck an excellent balance and it is hard to imagine who, among those interested in the many biological, chemical, clinical and veterinary aspects of reproduction, will not want to have *The Biochemistry of Semen and of the Male Reproductive Tract* on their bookshelves.

ROTHSCHILD

## CELLULAR BIOLOGY FOR THE LAYMAN

### The Life of the Cell

Its Nature, Origin and Development. By Prof. J. A. V. Butler. Pp. 167+16 plates. (London: George Allen and Unwin, Ltd., 1964.) 30s. net.

AT the present time there is a strong movement towards unity in biology, stimulated by the dramatic advances of the past decade, which have led to the establishment of new unifying concepts, the most fundamental being the evidence for the universality of the genetic code. Several books have appeared recently in which attempts have been made to compile this recent information systematically. To the layman (for whom this volume is mainly intended) the cell probably provides the most tangible starting point and Prof. Butler has chosen this approach. The present book might be considered a second edition of his earlier one entitled *Inside the Living Cell*, except that so much has happened in the past five years that it has had to be very extensively re-written.

The range covered is enormous, extending from elementary chemistry to the working of the brain. The author first considers the structure of biological macromolecules (proteins and nucleic acids) and manages to do so without introducing many chemical formulae. For those who are interested in these he provides an appendix. He goes on to discuss in some detail the replication of DNA and the synthesis of proteins. There is then a logical development towards a discussion of the genetic code, mutagenesis and the genetics of micro-organisms. At this point the difficulties of developing a logical exposition of this subject become apparent. A chapter on photosynthesis becomes interposed between a chapter on the genetics of micro-organisms and one on the origin of life; this is followed by one on differentiation and another on antibiotics. Later chapters deal mainly with questions concerning multicellular organisms (especially mammals) rather than problems of the cell. They include a consideration of immunity, a discussion of cancer and chapters on the brain and sense organs, nerves and muscle. There is a final chapter dealing with the possibility of life being distributed widely throughout the universe. The book therefore covers a much wider range than its title suggests. Facts are generally reported with impeccable accuracy; the only statement to which I could take serious exception is the definition of leukaemia on p. 63.

Non-essentials have been trimmed away and the essentials of even rather abstruse concepts described in a manner which should certainly be comprehensible to anybody who has studied any aspect of science and even, I believe, to the intelligent and intellectually curious student of the humanities. Hence, besides being a good general introduction to present-day problems in biology, this is just the kind of book which might help to bridge the gulf between the two cultures. One hopes that some journals commonly read by students of the "other culture" will also undertake to review it.

J. PAUL

## LABORATORY PROCEDURES IN BOTANY

### Laboratory Techniques in Botany

By M. J. Purvis, D. C. Collier and D. Walls. Pp. viii+371. (London: Butterworth and Co. (Publishers), Ltd., 1964.) 57s. 6d.

THE great importance of the work of technicians in running a modern botanical laboratory is perhaps not always fully appreciated. It is so often taken for granted that technicians are always there and that they somehow or another seem to know how to deal with every

practical problem that arises in the research and teaching laboratory as well as on the demonstration bench. Nevertheless, in spite of the great knowledge that many botanical technicians possess, it is unusual to find them writing books that give practical directions for laboratory procedures. We are therefore greatly indebted to the three authors of the book under review, all of whom are laboratory technicians, for giving us in writing the benefit of their first-hand experiences of a very wide range of laboratory methods. The topics that are covered range from cleaning glassware to histological and cytological procedures including those in use for electron microscopy. Tests for the chemical nature of cell walls and cell contents are also given. But the book is by no means restricted to microscopical techniques for there are chapters dealing respectively with the preparation of material for museums and herbaria; the care of plants in aquaria; the raising of organisms and the growth of tissues in pure culture. There are also directions for setting up demonstration experiments dealing with growth, photosynthesis, and respiration, while topics such as manometry, chromatography, and distillation techniques are also covered and directions given for the analysis of soils, water and plant material. The book also includes a selection of questions from the Advanced Level Examination for the General Certificate of Education, and others from the City and Guilds examinations for laboratory technicians. The volume ends with an index.

Naturally it has not been possible to treat all these as well as other topics exhaustively in a book of 371 pages, but references are given to literature for further study. It is likewise almost inevitable, with a book of this kind, that specialists will feel that one or more of their own pet methods have been omitted or are inadequately treated. Others again may feel that they would have preferred slightly different methods. To me, for example, it seems that in the excellent treatment of histological procedures insufficient attention has been directed to the many purposes for which the sledge microtome can be used. This very versatile instrument can in fact be used not only to cut sections of timber and other hard material as the authors rightly suggest, but it is also equally satisfactory for herbaceous specimens, including leaves, held in the clamp between pieces of pith or cork. All this can be done without having to resort to lengthy embedding techniques. Another very useful addition would be a few paragraphs on the histological examination of dried material such as herbarium and archaeological specimens. Then again, in my own experience, very few technicians seem to have discovered that compressed material that has been preserved in wet anaerobic conditions can be examined more successfully by cutting sections and then 'reviving' them rather than by 'reviving' the material before the sections are cut.

In spite of inevitable minor omissions such as the examples just given, the book is a most valuable contribution to botanical literature and it will no doubt be widely welcomed, especially on account of its broad content.

C. R. METCALFE

## INSECT PHYSIOLOGY

### The Physiology of Insecta

Vol. 1. Edited by Morris Rockstein. Pp. xiv+640. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 157s.

THE publication of Wigglesworth's *Principles of Insect Physiology* twenty-five years ago has resulted in a flood of valuable works in this field of investigation. Volume 1 of *The Physiology of Insecta* is the first of three large books in which it is planned to cover the field again. The editor, Morris Rockstein of the University of Miami, has selected a team of authors more than half of whom

are from universities in the United States. There is no overlap in authorship, and so far almost none in content, with the first volume of *Advances in Insect Physiology* published by Academic Press, the authors of which are mainly from England and treat narrower fields, chosen mainly for their timeliness and general interest.

Rockstein's plan is to consider insect physiology in a way not hitherto attempted, in three main sections (which do not correspond with the three volumes). Section A deals with the development of the insect from that of the egg in the ovary through moulting and metamorphosis up to senescence; Section B with perception and reactions to the environment; Section C with the homeostatic processes which include nutrition, excretion, water balance and immunology. Volume 1 completes the consideration of Section A with an introduction and five chapters on reproduction, metamorphosis and ageing, with emphasis on their endocrine control. Half Section B is also included and this has chapters covering the effects of temperature and humidity, the production and detection of light and sound, and the structure and function of the chemoreceptors.

The chapters contain many new diagrams and tables and include many valuable graphs and photographs, the style of writing is generally clear, and the subject is treated in a very stimulating manner, like an uninhibited account of an incomplete exploration in which the goals are still only imperfectly comprehended. The book has been produced with remarkable speed so that some of the references are to papers of 1963. However, the bibliographies to some of the chapters suggest that the authors have limited access to periodicals in languages other than their own, and it is probably a symptom of hurried production that the proof reading has been careless. The index to scientific names has a number of entries out of place and more than 3 per cent of the entries are wrongly spelt.

Many readers will be surprised to find that long-accepted stories, like Exner's explanation of insect vision, are based on erroneous observations and are no longer acceptable. Perhaps the main impression this book leaves is of a vast amount of information digested and critically summarized. This information is so much more substantial than that available, say, to Roeder and his team eleven years ago that many new generalizations are now possible. If the two volumes to follow reach the same high standard, this book should be extremely valuable as a source of fact and speculation to research workers and teachers in the universities of the world. G. C. VARLEY

## MAMMALIAN COCHLEA

### The Organ of Corti

*Its Histophysiology and Histochemistry.* By Ya. A. Vinnikov and L. K. Titova. Authorized translation from the Russian by Basil Haigh. Pp. xix + 253. (New York: Consultants Bureau, 1964.) 13.50 dollars.

THE authors of *The Organ of Corti* have clearly taken as their objective a modern and comprehensive presentation of information relating to the anatomy and physiology of the mammalian cochlea. In many ways they have achieved success. Almost every aspect of the subject is surveyed in a competent and analytical manner, and the results are then used for the synthesis of a new cytochemical theory of hearing.

In Chapter 3 a particularly valuable description is given of the technical methods used for the dissection and preparation of the cochlea for its examination by modern methods, using phase-contrast and electron microscopy and also the various histochemical techniques. It should perhaps be mentioned that many of these methods of dissection are not new and might, in fact, be described

as the technical stock-in-trade of all, including Retzius, who have devoted themselves to the investigation of the microstructure of the cochlea. Nevertheless, the authors are right in emphasizing that no systematic description of their methods is available, and in providing it they undoubtedly do a great service. The chapter is particularly relevant in view of the great and growing importance of the new microscopical techniques for which the methods of preparation are essential.

As judged by their previous publications, the primary interest and expertise of Vinnikov and Titova lie in the difficult field of histochemistry, and it therefore seems natural that a large part of the book should be devoted to the description and evaluation of their own contributions. However, for a proper assessment of their impact on our concept of the cochlear mechanism, these must of necessity be considered in a balanced relationship to the multitudinous data which have now been put at our disposal through the allied investigations of anatomists, physicists and neurophysiologists.

The authors clearly appreciate the need for this kind of synthesis, and strive to achieve it at every stage. However, their success is not absolute, and Hallowell Davis, in the course of his valuable preface, directs attention to apparent anomalies in the physical conditions of certain experiments concerned with the histochemical changes in the cochlea following acoustic stimulation.

The book has a certain arresting vigour which it must owe in large part to the eminence, as investigators, of the authors themselves, and this is reflected by the way in which thought and argument seem to be coloured by their own observations. Bias of this kind is sometimes irritating; nevertheless, it has in this case undoubtedly lent interest and authority to the presentation of an important and complex subject, the value of which has been greatly enhanced by an exceptionally meritorious English translator.

All in all, the book can only be described as a quite remarkable achievement for which its authors and translator are to be warmly congratulated. It will be welcomed by and invaluable to all who are interested in the scientific investigation of the organ of hearing.

C. S. HALPKE

## "THAT OLD ENEMY THE GOUT"

### A Short History of the Gout and the Rheumatic Diseases

By W. S. C. Copeman. Pp. ix + 236 + 19 plates. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1964.) 6 dollars; 48s. net.

DR. COPEMAN has special qualifications for writing this book, which is partly an expansion of a lecture he gave to the University of California in 1962. As a physician he has had extensive experience of gout and the rheumatic diseases; in addition, he is well known for his studies and investigations in medical history. When experts investigate a branch of medicine which they have made pre-eminently their own, their writings for this very reason are the more authoritative and valuable.

The first seven chapters deal with the history of gout from the earliest times to the recent chemical discoveries in the present century, such as carinamide and probenecid, an improved and non-toxic form replacing atophan in 1951. Probenecid and later synthetic variants have the power of inducing in the body a negative urate balance, either by influencing the production of uric acid, or, as is more likely, by stimulating the kidneys to part with it more readily. This new knowledge challenges Sir Alfred Garrod's simple conception of uric acid as the main cause of the disease. As the author states (p. 117): "It is becoming increasingly evident, however, that gout is the

end product of a disordered body metabolism, which is often genetically acquired".

The remaining five chapters of the book deal briefly but succinctly with acute rheumatism and chorea, rheumatoid arthritis, ankylosing spondylitis, osteoarthritis and non-articular rheumatism or fibrositis. Here there is much information both clinical and historical within small compass. Most interesting is the account Dr. Copeman gives of notable sufferers from the arthritic diseases, and of the way in which their maladies have influenced the course of history.

As regards gout, the great Renaissance family of Medici exemplified the association between outstanding ability and the gouty diathesis. The Emperor Charles V's recurrent attacks of gout, fostered by his gluttonous and huge appetite, through consequent incapacity and delay, affected the course of State affairs and his conquests. This was also the case with his son, Philip II, who inherited the malady. Other victims were Martin Luther, John Calvin and William Cecil, Lord Burghley. Burghley's frequent attacks probably influenced his outlook and policy. His son, Robert Cecil, Earl of Salisbury, also suffered from gout. The unfortunate Earl of Strafford had attacks of both gout and stone. Additional gouty patients were Sydenham, Sir William Temple, Francis Bacon, William Harvey, John Milton, William Penn, Dr. Johnson, the elder and the younger Pitts, Edward Gibbon, Horace Walpole, Thomas Gray, Benjamin Franklin; and coming to modern times, we may add Joseph Chamberlain and his son, Neville Chamberlain. Rheumatoid arthritis claims such celebrated sufferers as Pope Pius II, Christopher Columbus, Mary Queen of Scots, President Madison of the United States, and Renoir, the French artist.

Dr. Copeman in this book has made an important contribution to medical history. The illustrations are excellent and accord well with the text.

## ADVANCES IN ORGANIC CHEMISTRY

### Advances in Organic Chemistry

Methods and Results, Vol. 3. Edited by Ralph A. Raphael, Edward C. Taylor and Hans Wynberg. Pp. vii+333. 105s.

Methods and Results, Vol. 4. Edited by Ralph A. Raphael, Edward C. Taylor and Hans Wynberg. Pp. vii+361. 110s.

(New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1963.)

**A**MONG the multiplicity of alerting media available to chemists to enable them to keep abreast of developments in their respective fields of interest, reviews are proving ever more popular by virtue of their time-saving nature. These critical digests of pertinent data and evaluations of present-day progress in selected fields provide valuable sources of up-to-date information and extensive bibliographies, and are now generally accepted as a basic unit in scientific communication. In addition to the review journals issued by the scientific societies, serial review volumes are now issued regularly by some of the publishing houses under advisory and editorial boards comprising people of eminent standing in their field. The volumes under review belong to one such series. Two volumes have appeared earlier and they have found wide acclaim. In these two additions to the series again there has been a judicious selection of topics and a happy choice of authors.

Four themes are discussed in Volume 3—mass spectrometry as a structural tool (R. I. Reed), phosphorylation (D. M. Brown), selectively removable amino protective

groups used in the synthesis of peptides (R. A. Boissonnas), and protective groups (J. F. W. McOmie). It is entirely fitting that the new tools of the organic chemist, which are responsible for so many advances in the science, should be featured. The availability of high resolution mass spectrometers has provided the organic chemist with a very powerful and sensitive structural and analytical tool. The many and varied uses of the mass spectrometer are reviewed and illustrated with some well-chosen examples. The cracking patterns observed on the fragmentation of molecules are correlated with known structural features in the molecule. Certain useful generalizations are made but some important exceptions are noted. The ambiguities resulting from the occurrence of rearrangement ions and the difficulties of deducing the nature of the neutral fragments are stressed; these call for caution in the interpretation of the spectra. Notwithstanding the complications, some striking progress has been made in the analysis of spectra for structural elucidation and this aspect is treated in detail with reference to some dozen representative molecular structures.

In the course of his synthetic experiments the organic chemist often has to resort to the use of protective groups. These are designed to protect certain reactive groups or radicals in the molecule while another part is made to undergo chemical reaction. The synthesis of some complex molecules requires the use of several different protective groups which must be capable of selective removal one after the other under mild conditions. A valuable survey of the methods for introducing and selectively removing groups which are needed to protect the amino group in peptide synthesis is presented. Due emphasis is placed on the stability and general resistance to racemization of these groups under the conditions usually employed for the formation of peptide bonds. There also appears, for the first time, a comprehensive review of the use of protective groups (other than those noted above) throughout the broad field of organic chemistry. This contribution will be much appreciated. As the author points out, there is no systematic way of scrutinizing the literature for protective groups, and although he modestly claims that inevitably some protective groups will have been missed the coverage is extremely wide and reflects a very catholic knowledge of organic chemistry. It is interesting to read that certain cockroaches also make use of protective groups for biosynthesis!

Phosphate esters are found in enormous variety in and truly dominate the chemistry of living systems. Generally polyfunctional and often labile, the synthesis of the more complex systems of biochemical interest also necessitates special protective measures. These are covered in the chapter on "Phosphorylation", which also includes a broad survey of phosphate ester chemistry and phosphorylation methods generally.

Volume 4 is devoted to three topics—enamines (J. Szmuszkovicz), synthetic methods in the carotenoid and vitamin A fields (O. Isler and P. Schudel), and the coupling of acetylenic compounds (G. Eglinton and W. McCrea). It is only in the past ten years that the full chemical potentiality of the enamines, the structural moiety represented by  $\alpha\beta$  unsaturated amines, has been realized. In a wide-ranging survey, the synthesis, reactions and physical properties of enamines and some dienamines are discussed and the applications of enamine chemistry to a variety of problems are strikingly portrayed. An appendix listing the titles of some 43 relevant papers which appeared between the writing of this chapter and the publication of the book illustrates the *tempo* of present-day research activity in this field.

The chemistry and stereochemistry of vitamins A and A<sub>2</sub> and the related carotenoids are now firmly established and total syntheses have been achieved. The main methods used in the synthesis of these complex systems and the key intermediates are presented in a novel and systematic way by two members of a school which has

been conspicuously associated with these outstanding achievements. Various chain-lengthening methods, which have played an important part in the synthetic investigations, are prominently featured and stereochemical considerations receive due attention.

The last chapter deals with the oxidative coupling of acetylenes through the intermediacy of the cuprous derivatives. Discovered by Glaser some 90 years ago and applied by Baeyer in 1882 in his historic synthesis of indigo, this reaction, in its various modifications, has proved of great utility. It has figured in the synthesis of naturally occurring polyacetylenes and has been elegantly applied for the synthesis of a whole range of novel, unsaturated macrocycles including the first all-planar, cyclic homologue of benzene, [18]-annulene. The full scope and versatility of this reaction are clearly demonstrated in this review. However, one is left with the impression that much remains to be learned concerning its mechanistic aspects. While it has been brilliantly exploited by the organic chemists for preparative purposes it has been very much neglected by physical chemists and co-ordination chemists. Maybe this critical appraisal of the present state of knowledge will inspire fresh endeavours to shed more light on the course of these acetylene coupling reactions and the not unrelated oxidative coupling of phenols and aromatic amines by the same reagents.

The declared motto of one of the reviews is "to stimulate rather than to satisfy". Every single contribution will certainly not fail to stimulate and most, if not all, organic chemists will feel more than satisfied with the wealth of well-documented and systematically presented information which has been crystallized within these pages.

J. IDRIS JONES

## MÖSSBAUER SPECTRA AND CHEMICAL STRUCTURE

The Mössbauer Effect and Its Applications in Chemistry  
By V. I. Gol'danskii. Authorized translation from the Russian. Pp. vii+119. (New York: Consultants Bureau, 1964.) 12.50 dollars.

THE effect of recoil-less emission and resonant reabsorption of  $\gamma$ -rays was first reported by Rudolf Mössbauer in 1958 and it has already been used for a wide variety of elegant experiments in basic physics. During the past three years it has been increasingly recognized that the Mössbauer effect can also give valuable information on chemical problems, and one of the pioneers in this field, Prof. V. I. Gol'danskii, has now written the first monograph specifically aimed at describing these chemical applications. The treatment throughout is non-mathematical and eminently readable.

The account begins with a brief discussion of the energies and widths of resonance transitions. When an excited atom is bound in a crystal the  $\gamma$ -ray may be emitted without recoil or thermal broadening and the precision with which its energy is then defined depends only on the Heisenberg uncertainty relation. Energy quanta of unprecedented precision are therefore available and these have been used to probe the minute changes in the separation of the nuclear energy-levels which result from differing chemical environments. These ideas are developed in the second chapter, which also mentions briefly the appropriate experimental techniques.

In any spectroscopic technique, information can be derived from the number of lines observed, from their position, shape and intensity. In Mössbauer spectroscopy these parameters give information about chemical shifts, quadrupole coupling constants and hyperfine magnetic fields. The origin of these effects is traced in Chapters 3 and 4.

The Mössbauer effect has been detected in a large number of elements with atomic numbers greater than 26 and these elements are spread widely throughout the Periodic Table. The most extensively investigated nuclide is  $^{57}\text{Fe}$  and results on the compounds of iron are reviewed in Chapter 5. Alloys, mixed oxides, salts, co-ordination complexes and organometallic compounds are mentioned.

Compounds of tin have also been widely investigated and the results are discussed in Chapter 6. This is followed by an assessment of various other problems which might be tackled by Mössbauer spectroscopy. There is an appendix listing the relevant properties of some eighty nuclides of the forty-five elements for which resonance has been observed or is predicted, and the review ends with a supplement outlining results published during 1963.

Prof. Gol'danskii has provided us with a persuasively written and exciting account of this new technique and it is unfortunate that his efforts have not been matched by those of the publishers. The translation, though generally good, is marred by occasional oddities like "gamma transactions", "very weakly pronounced" and "defectoscropy". The typesetting is also variable in quality and it is difficult in places to distinguish between  $\Gamma$ ,  $\gamma$ , and  $r$ . The binding is inadequate and the price very high. The original Russian publication cost about 30 cents and an English translation is already available from the International Atomic Energy Agency, in Vienna. There is a further disturbing feature: this is a 65-page review which is being made by the publishers to masquerade as a 120-page book. There is no indication from the title on the cover, from the fly-leaf, from the title page itself, or from the author's preface that half the book has nothing to do with the Mössbauer effect but is a translation of a four-year-old paper on another subject by other authors, whose names do not even appear in the table of contents.

N. N. GREENWOOD

## WIDENING FIELD OF QUANTUM ELECTRONICS

### Quantum Electronics

Proceedings of the Third International Congress. Paris. Edited by Prof. P. Grivet and Prof. N. Bloembergen. Vol. 1: pp. xxix+1-966. Vol. 2: pp. 967-1923. (Paris: Dunod, New York and London: Columbia University Press, 1964.) 252s. the two volumes.

QUANTUM electronics is a term which was originally coined to cover the investigation of resonant phenomena associated with the interaction of radiation and matter. With the growth of new techniques has come an inevitable spreading of the boundaries of the subject. Some of the topics are new, such as non-linear optical effects and the stimulated Raman effect; in others interest has been revived. The development of the maser is responsible for a great part of this growth, particularly in its optical form, the laser.

The third international conference on "Quantum Electronics" was held in Paris in February 1963. (The term 'Congress' is used only on the title page of the *Proceedings*.) There were some 1,100 participants, compared with 160 at the first conference in September 1959, and 450 at the second in March 1961, ample evidence of the growth of interest in the subject. In all probability this will be the last conference of this nature; no suitable accommodation is available for the numbers that are likely to wish to attend in future.

There has been a long delay in the publication of the *Proceedings* of the conference, but the result has been well worth the wait. Two hundred of the papers presented at the conference are published, thirty-two of them in French, the rest in English. Among the new topics that

are treated in detail are the theory of the coherence properties of light, laser modes and cavity design, semiconductor and phonon lasers, and non-linear optics. The rest of the papers are grouped in the sections on optical pumping and magnetometers, molecular beam masers, gas lasers, the spectroscopy of solid-state materials, solid-state masers and solid-state lasers. It is clear that the laser is responsible, directly or indirectly, for about half the papers.

From such a wealth of material it is scarcely possible to choose a few papers for special mention. It is adequate to say that the papers in each of the ten sections make each an invaluable survey of its particular field. The conference attracted leading experts, many of whom gave survey papers covering their own subjects, among them E. Wolf, J. Brosel, N. F. Ramsey, W. R. Bennett, jun., C. G. B. Garret and P. A. Franken. Particularly valuable is a record of the discussion which followed each paper, and the editors are to be congratulated on their success in persuading the authors to present their published papers in full, and not merely in skeleton form. A useful luxury is appended to a few of the papers in the form of a summary, sometimes in the language of the paper and sometimes in the second language of the conference. The value of the *Proceedings* would have been considerably enhanced if short summaries of all the papers could have been given in both English and French, but one can appreciate the magnitude of the editors' task in achieving this ideal. Inevitably the price of the two volumes is formidable, but entirely commensurate with their value.

J. H. SANDERS

## DEEP-SEA SANDS, GREYWACKES AND FLYSCH

### Turbidites

Edited by A. H. Bouma and A. Brouwer. (Developments in Sedimentology, Vol. 3.) Pp. 264. (Amsterdam, London and New York: Elsevier Publishing Company, 1964.) 90s.

WITH an ever-increasing number of sedimentologists working in flysch and greywacke sequences, a book on turbidites will inevitably arouse interest. This volume consists of fourteen articles together with an introduction and a final summary. In the first article, Prof. Kuenen, who introduced the term 'turbidite' into geological literature and who is largely responsible for the present popularity of the turbidity-current hypothesis, considers the evidence for the origin of deep-sea sands and their possible ancient equivalents. Two further articles are concerned with modern sands in the Adriatic and the Mediterranean; another two pay some attention to methodology. Regional accounts of geosynclinal successions with flysch and greywackes are given from the Apennines, Britain, the Central Carpathians, Germany, the Maritime Alps and the United States. Points of sedimentary detail are described in another two articles and a comprehensive bibliography of turbidite literature has been compiled.

Kuenen presents a powerful restatement of the turbidity-current hypothesis as applied to the interpretation of deep-sea sands, flysch sandstones and greywackes. He also includes some penetrating criticism of alternative suggestions which have been made for the origin of these sediments.

Stanley and Bouma advocate the systematic examination of sedimentary features and the recording of data graphically and on punch cards preparatory to analysis using the digital computer. They go on to give an account of a palaeogeographical reconstruction using the 'multiple parameter' method which they have described. The reconstruction, however, differs in no obvious ways from others prepared over the past decade (for example, the

excellent palaeogeographical atlas of the Polish Carpathians) which do not claim to involve anything more than traditional methods. Or is it that sedimentologists have been using the 'multiple parameter' method all this time without realizing it?

The regional accounts vary from detailed analyses to short articles which are little more than bibliographical lists. The palaeogeographical reconstructions from the Maritime Alps (Stanley and Bouma) and the Central Carpathians (Marschalko) are very valuable examples. Meischner presents a detailed investigation of calcareous turbidites (called 'alldapic limestones') in which the sedimentary features are interpreted in terms of a model of sedimentation similar to schemes already suggested. Among other data from Britain, Kelling makes special mention of the frequent divergence in the current directions of sole markings and, a little higher in each bed, transverse ripples. In addition to recognizing the possibility of the reworking of turbidite deposits by bottom currents Kelling suggests that surge waves resulting from the passage of the turbidity current may have been responsible for the transverse ripples. With gradually accumulating evidence for the operation of bottom currents in present-day deep-waters, this problem of ripple-mark versus sole mark direction is likely to provide the basis for much future discussion. Spotts and Weser find that there may also be a discrepancy between grain-orientation and sole markings. Is this an aspect of the same problem—an interaction of turbidity-current flow and bottom currents or the effect of reflected surge waves?

Granted the operation of both types of current, how are the turbidites to be distinguished from those sands deposited from bottom currents? Massive graded beds without large-scale current bedding would appear to be typical of turbidites especially if, as Meischner points out in his investigation of the alldapic limestones, current sole markings, bed thickness and grain-size show some intercorrelation. But the distinction is very difficult when laminated and rippled fine-grained sandstones are considered. Van Straaten, following Bouma, maintains that the lamination sequence, parallel-ripple and convolute-parallel, is diagnostic of turbidites, but this would be regarded with some scepticism by other workers. Rizzini and Passaga contend that grain size analyses using the CM method developed by Passaga can be used to separate turbidite from traction deposits. This method has, however, the disadvantage that it can only be applied to sequences of sandstones.

The foregoing remarks will show that there is much of value in *Turbidites* and the specialist will find a number of papers well worth reading. There are, unfortunately, a number of features to be deprecated. The quality of some of the plates is deplorable and typographical errors can be found throughout the volume. Many readers will welcome the fact that some of the foreign authors have presented their work in English. It is clear, however, that some of these writers needed to rely heavily on editorial help in clarifying and correcting their work; this help was apparently not provided and some of the text is ambiguous or obscure.

There is, too, a vast unevenness of treatment. Does, for example, a paper describing an outcrop of one bedding plane, 10 square yards in extent and describing one small feature of sedimentation, merit 30 pages when the turbidites from the rest of the United States are treated in 12? Again, ten Haaf's provocative little paper on the Apennines raises a number of complex questions which I at least would have liked to have seen developed.

Perhaps the clue to the unevenness lies in the fact that the papers were initially gathered together to form a special issue of *Sedimentology*. The collection remains a series of papers for a journal and, however valuable some of them are individually, they do not form a satisfactory book—not at the price of £4 10s.

E. K. WALTON

## *Homo 'habilis'* AND THE AUSTRALOPITHECINES

By PROF. J. T. ROBINSON

Departments of Anthropology and Zoology, University of Wisconsin, Madison 6, Wisconsin

LEAKEY, Tobias and Napier have given a preliminary account of specimens which in their opinion belong to a hitherto unknown species of the genus *Homo*<sup>1</sup>. They re-defined the latter genus and proposed the species name *H. habilis*, with definition, for the new taxon which includes specimens discovered between late 1960 and late 1963.

### Diagnosis of the New Taxon

Two critically important functions of the original description of a new taxon are: (a) to demonstrate that the population sample under discussion represents a taxon which is different from all recognized taxa and is therefore indeed new and in need of a name; (b) to place on record the new name selected for the taxon.

In order that the first of these functions be satisfied a differential diagnosis is necessary. This brings out the points of difference between the specimens comprising the new taxon and all closely related specimens which have been referred to already existing taxa. From this point of view the original description of *H. 'habilis'* by Leakey *et al.* is unsatisfactory. Doubtless the authors intend to present further evidence elsewhere at a later date, but clearly the appropriate place is in the original description (in the technical taxonomic sense) so that others may judge the validity of the proposed taxon.

The proposed new definition of the genus *Homo* depends in part on the validity of the new species proposed for it. The new species is defined briefly as though proof had previously been presented that it is a new taxon—but in fact there is no discussion of 'evidence' which clearly establishes that this is the case. The definition does include a few very broad diagnostic comparisons, for example, "... premolars which are narrower (in bucco-lingual breadth) than those of *Australopithecus* . . .", but no evidence is presented to support them.

Furthermore, although reference is made to some previously known specimens with which the authors think their new species may be conspecific, no comparisons with the new material are actually included in their original description. In fact the following very curious statement is made: "The specimens originally described by Broom and Robinson as *Telanthropus capensis* and which were later transferred by Robinson to *Homo erectus* may well prove, on closer comparative investigation, to belong to *Homo habilis*". This statement clearly implies that the authors described a new species even though they believe that proper comparative investigation may well show that it is conspecific with specimens of which they are aware, the originals of which two of the authors have seen more than once and of which detailed descriptions exist in the literature. It is of interest also to note that the authors think that if the conspecificity be established in this case, then the material which was described more than a decade ago would belong to their new species rather than the other way about—as required by the *International Code of Zoological Nomenclature*.

One may thus conclude that: (a) the authors have not demonstrated that their proposed new species is in fact new; (b) the authors themselves are in doubt whether it is new; (c) since the validity of the new species has not been established, that of the new definition of *Homo* has not been established either. (In this general connexion see also the recent comment by Oakley and Campbell<sup>2</sup>.)

### Validity of the proposed New Species

Although the authors do not present evidence in support of the few suggested differentially diagnostic features separating the proposed new species from the australopithecines, it is worth enquiring into the validity of these features.

Evidently a character which has impressed the authors as significant<sup>1,3</sup> is "a marked tendency toward the buccolingual narrowing and mesiodistal elongation of all the teeth, which is specially evident in the lower premolars . . . and in the lower molars . . .". In particular it is held that the lower premolars are narrower than those of *Australopithecus* but fall within the range of *Homo erectus*. Through the courtesy of Dr. and Mrs. Leakey I was able to make a fairly detailed investigation, in 1961, of the mandible which has now been designated the holotype of *H. 'habilis'*. My measurements of  $P_3$ , made in the same manner as those on the South African australopithecines used for comparison, gave the following mesiodistal lengths and buccolingual breadths in millimetres: left,  $9.6 \times 9.4$  and right,  $9.6 \times 9.9$ . These figures yield length/breadth indices ( $L \times 100/B$ ) of 102.2 and 98.0 respectively. Leakey<sup>3</sup> lists these dimensions as  $11.0 \times 9.5$  in both cases and the index as 115.8. However, as comparison is being made with measurements made by me on the South African australopithecine material, my measurements on the Olduvai specimen should yield a better comparison since all the measurements involved were made by the same person using the same technique.

The table compares the mean length/breadth index and the observed range of the index for  $P_3$ ,  $M_1$  and  $M_2$  of *Paranthropus*, *Australopithecus* and Pekin Man (*Homo erectus*) with the corresponding values for the type mandible of *H. 'habilis'*.  $P_3$  of the latter falls within the observed range of that for *Paranthropus* and not far outside that for Pekin Man. The fit is slightly less close with *Australopithecus*; but the sample for this form is made up of only four specimens representing three individuals. The highest value listed for *Paranthropus* belongs to a tooth which had not yet begun to erupt and the final dimensions would possibly have been slightly higher than at present, although the length dimension already is very close to the upper limit for the sample of 12 specimens. However, since we are here concerned with proportions it is legitimate to include the value for this specimen as the crown is intact and undamaged and it is highly improbable that any slight increase in the crown dimensions that may have occurred before eruption would alter the shape so disproportionately as to change the shape index significantly.

In the case of  $M_1$ , the *H. 'habilis'* value falls slightly outside the ranges for *Paranthropus* and Pekin Man, but barely outside that for *Australopithecus*. Leakey<sup>3</sup> mistakenly quotes 114.6 as the highest observed and published value for *Australopithecus* (*sensu stricto*) and concludes that his value for the type mandible (117.0) falls outside that for *Australopithecus*. In the case of  $M_2$  the *H. 'habilis'* value falls within the observed ranges for both *Paranthropus* and Pekin Man and very slightly outside that for *Australopithecus*. In both cases the *Australopithecus* sample size is small.

In one section of the original description Tobias refers to a lower molar, of Hominid 4, which he believes to be either  $M_2$  or  $M_3$ , and writes: "The molar is 15.1 mm in

Table 1. LENGTH/BREADTH INDICES

	$P_3$			$M_1$			$M_2$		
	$N$	Mean	Range	$N$	Mean	Range	$N$	Mean	Range
<i>Australopithecus</i>	4	83.0	77.0-88.5	8	107.8	100.8-117.0	9	107.7	98.0-111.3
<i>Paranthropus</i>	14	85.2	76.0-112.3	19	106.2	100.7-110.8	12	108.4	101.4-117.3
<i>H. 'habilis'</i> type	2	100.1	98.0-102.2	2	117.2	117.2	2	114.3	114.3
Pekin Man	13	86.3	75.0-96.8	11	100.1	96.8-112.0	7	104.4	98.3-115.4

mesiodistal length and 13.0 mm in buccolingual breadth; it is thus a small and narrow tooth by australopithecine standards . . .". The length/breadth index of this tooth is 116.2; the observed range for *Paranthropus* is 101.4-117.3 for  $M_2$ , and 106.6-124.1 for  $M_3$ —indeed, the 'mean' index for the sample of 13 specimens for the latter tooth is 116.3. The ranges for this index for  $M_2$  and  $M_3$  of *Australopithecus* are 98.0-111.3 and 100.0-116.0 ( $N = 10$ ) respectively.

The size can best be compared by using the module so that single values can be compared instead of pairs. The module for the aforementioned Olduvai tooth is 14.05. This certainly is smaller than are either  $M_2$  or  $M_3$  of *Paranthropus*. However, the lowest modules for the small collection of these two teeth of *Australopithecus* are, respectively, 13.75 and 13.20. These figures thus show that the Olduvai hominid 4 tooth is neither exceptionally small nor exceptionally narrow by australopithecine standards.

This evidence, along with that from the type specimen, therefore does not support the contention that the shape characteristics of the *H. 'habilis'* mandibular teeth are recognizably different from those of the australopithecines. The *H. 'habilis'* specimens here considered have values which fall mostly toward the upper end of the ranges of variation at present available for the australopithecines. But it is very clear that in no case are adequate samples available: the ranges of variation are certainly smaller than they should be and insufficient is known about *H. 'habilis'* to know how representative the few known specimens are of the populations from which they came.

However, a far more trenchant criticism of the use made of the dental length/breadth index by Leakey *et al.* is that analysis of the index shows that it and the features on which it is based have extremely low phyletic valence so far as hominids are concerned. This is readily apparent from the extremely wide overlap of the ranges for this index for *Australopithecus*, *Paranthropus*, *Homo erectus* and *Homo sapiens*. It is not possible to distinguish taxonomically between these groups by means of this index if anything like adequate sample sizes are used. As may be seen from Table 1 the means for *Paranthropus* and Pekin Man are 85.2 and 86.3 respectively for  $P_3$  and (not shown in Table 1) values for samples of modern Bantu and aboriginal Australians differ from that of Pekin Man by a few tenths of a unit. Thus, populations covering so great a span of the hominids have means for this index which are very closely similar. On the other hand, various local populations of modern man have mean values for this index which actually show greater variation than the foregoing. That is to say, the intra-species variation in the mean in modern man is actually greater than the intergeneric differences in the mean for three populations of *Australopithecus*, *Paranthropus* and *Homo erectus*. Furthermore, these differences between the means are small compared with the range of variation observed within any one of the populations concerned.

The endocranial capacity of *H. 'habilis'* appears, on the scanty and indirect evidence available<sup>8,1</sup>, to have differed little from that of the australopithecines with a range overlapping that of the latter substantially.

The conclusion that the foot of the new form has a fairly advanced and *Homo*-like structure while the hands appear to have been relatively more primitive does not

help a great deal at present since not much evidence of these parts is available for either australopithecines or *H. erectus*. However, neither conclusion should occasion astonishment. If the australopithecines were erectly bipedal in posture and locomotor habit, as much evidence suggests, then the foot was being used in an essentially human fashion and is likely to have achieved a relatively advanced structure soon after the new locomotor habit was achieved. On the other hand, neither the australopithecines, as apparent tool-users, nor *H. 'habilis'* as an apparent primitive tool-maker, were culturally advanced and therefore one might expect that the moulding of the hand under the influence of manipulative activity of the human sort was not far advanced. Thus one might expect the foot to have had a more modern-looking structure than the hand in both the australopithecine stage and the early hominine stage. The apparently fairly advanced foot of *H. 'habilis'* does not therefore necessarily indicate affinity with *Homo* rather than *Australopithecus*—indeed, the fact that a striding gait appears to be inconsistent with the morphology of the *H. 'habilis'* foot<sup>9</sup> suggests that it is unlikely to have been significantly more advanced than that of *Australopithecus*.

In view of the foregoing it seems to me that Leakey *et al.*, in their original description of *H. 'habilis'*, have by no means provided a reasonable case for establishing a new species of *Homo* to accept the recently discovered Olduvai specimens. Furthermore, some of the distinguishing criteria used do not appear to be valid for the purpose in the light of available knowledge of early hominids.

#### Affinities of *H. 'habilis'*

In assessing the material attributed to *H. 'habilis'* it must be remembered that two groups of specimens are involved: one from Bed I and the other from Bed II. On the available dating evidence these two groups are separated by a significant time gap.

The morphological characteristics of the two groups are not the same. This is well shown, for example, by comparing the type mandible from FLKNN I with the mandible from MNK II (see Leakey and Leakey<sup>5</sup>, Fig. 3). I have elsewhere<sup>6,7</sup> discussed the shape of the internal mandibular contour, seen in occlusal view, and its narrow V shape in both types of australopithecine but its relatively wide U shape in *Telanthropus* and all other forms of *Homo*. The type *H. 'habilis'* mandible is damaged near the symphyseal region so that the partial right side has been displaced toward the left. However, the midline can be determined within very narrow limits and the internal contour of the left half is intact and undisturbed from very near the symphysis to a point behind  $M_2$ . It is therefore simple to reflect this contour on to the right side in a graphic reconstruction in order to determine the correct original position of the displaced right half. Carrying out this procedure shows that the type mandible had a typically australopithecine internal mandibular contour with the corpus thickness in the premolar region greater than the distance between the two halves of the mandible in that region. This is actually readily apparent on visual inspection since the corpus mandibulae is relatively thick compared with the breadth of the crowns of the teeth and much of this breadth is mesial to the teeth in the premolar region. In contrast the mandible from MNK II does not have this narrow V-shaped contour but

has the wide U-shaped contour and relatively thin corpus of the sort normal for *Homo*. The more recent, Bed II mandible thus agrees with *Homo erectus*, including 'Telanthropus', in this feature as well as its generally greater gracility, while the older Bed I mandible falls within the observed range of australopithecines in both respects. It is therefore by no means clear that the Bed I and Bed II groups of specimens necessarily belong to the same species.

The teeth of the type mandible show that the australopithecine affinities of this mandible are very clearly with *Australopithecus* and not with *Paranthropus*. The latter is characterized among other things, as witnessed by the South African, East African and Indonesian evidence, by a small canine as compared with the size of the premolars, especially in the mandible. Indeed, the lower canines of this form are so small that they fall within the observed size range for modern living man while the premolars are the largest known among fossil and modern hominids. *Australopithecus*, on the other hand, has relatively large lower canines, *Sts 3* from Sterkfontein being one of the largest hominid mandibular canines known, but the premolars are smaller than those of *Paranthropus*. Thus the relative size of canine to  $P_3$  in the mandible is very different in the two australopithecines and any individual mandible can be assigned to the correct genus without hesitation on visual inspection if these teeth are present. The *H. 'habilis'* canine to  $P_3$  ratio is like that of *Australopithecus* and quite unlike that of *Paranthropus*. This fact is further supported by greater morphological resemblance in general between the teeth of the Olduvai specimen and those of *Australopithecus* as compared with *Paranthropus*.

On the other hand, the Bed II mandible shows much greater resemblance to the 'Telanthropus' mandibles, but the latter can easily be distinguished from the Bed I type mandible.

In terms of the available evidence it would seem that there is more reason for associating the Bed I group of specimens with *Australopithecus* and the Bed II group with *Homo erectus* than there is for associating the Bed I and II groups with each other. This would therefore seem a perfectly reasonable course to adopt: placing the Bed I material as advanced representatives of *Australopithecus africanus* and the Bed II group as somewhat early members of *Homo erectus*.

However, the Bed I and II groups of specimens occurred in the same geographical area, both appear to have been tool-makers and there seems no obvious morphological reasons why the earlier group could not have been ancestral to the later group. Furthermore, it seems unlikely in terms of ecology and behaviour that two morphologically similar groups, both adapting at least to a significant extent by cultural means, would develop in the same general geographic area. Clearly at least two hominid lines did in fact exist simultaneously in this region: the material under discussion and *Paranthropus* (= 'Zinjanthropus'). But in this case the *Paranthropus* line consisted of forms which differed markedly in morphology and evidently also in ecology and behaviour not only from the *H. 'habilis'* material but also all other known hominids. If the Bed I and Bed II groups represented two different lines, this would indicate not only that they would be adaptively similar but also that three different hominid lineages existed in the same area. For these reasons it seems probable that they actually do represent the same lineage at two different time levels. If this is so, then it is reasonable to place them in the same species. On the other hand, as already seen, morphological considerations favour their being placed in two different taxa which already exist, in which case they belong to two different genera. The evidence in favour of the latter course is actually the stronger.

The two interpretations do not have to be mutually exclusive: the Bed I material may represent an advanced

form of *Australopithecus* and Bed II specimens an early *H. erectus* and at the same time the latter may be a lineal descendant of the former. This seems to me to be by far the most probable interpretation. According to this hypothesis the Bed I specimens represent a transitional stage between *Australopithecus* and *H. erectus* just at that stage where the essentially tool-using stage of the former was giving way to the primarily tool-making condition of the latter. The widely held belief of recent years that *Paranthropus* at Olduvai was responsible for the stone implements found associated with it never did seem probable to me in the light of the available evidence from the Sterkfontein Valley. However, it seems far more probable that the *H. 'habilis'* material from Bed I represents the remains of the maker of the stone industry from that level.

If the interpretation suggested here is correct, then clearly no new species name is needed: the situation is simply one common in palaeontology when specimens are found which link two already existing taxa. Creating a new taxon here is no solution; the two taxa between which the new one falls are already so similar that insufficient morphological distance exists between them to justify the insertion of another species. As is well recognized, conventional Linnean taxonomy is not suited to dealing with a problem such as this and, if the hypothesis is correct, whatever solution is adopted must be a compromise of some sort. The more conservative approach would be simply to place the Bed I material in the species *Australopithecus africanus* and the Bed II specimens in *H. erectus*. However, if it is a fact that the Bed I specimens were already primitive tool-makers and were ancestors of the Bed II material, the implication that the ends of a transitional sequence, which involved relatively little morphological and ecological change and did not occupy a geologically long period of time, should be in different genera seems very unsatisfactory, especially as the transition was gradual and did not involve a threshold followed by rapid re-adaptation.

A reasonable way of overcoming this difficulty would be to extend the genus *Homo* to include not only the new Olduvai material but also that at present in the genus *Australopithecus* (as distinct from *Paranthropus*). This genus would then include the whole sequence from the point where a shift to an omnivorous diet (by the inclusion of a substantial degree of carnivorousness) caused a new set of selection pressures to come into play favouring the whole complex of culture as a means of adaptation and thus caused the emergence of culture-bearing man. This suggestion comes very close to one made a long time ago by Mayr<sup>10</sup>, but differs from it in not including *Paranthropus* since there is good evidence to indicate that the basic adaptation of the latter was quite different from that of the *Homo* lineage as defined here, a lineage which was separate from that of *Paranthropus* from at least early Pleistocene times as the evidence now clearly indicates. This difference is most conveniently indicated by a generic distinction. The known hominids would thus fall into the two genera *Paranthropus* and *Homo*.

If this were done, then it would seem to be useful to modify the species division at the same time so that the re-defined genus *Homo* includes only two species. Since these would belong to the same lineage they obviously could not be sharply defined. The first could be *H. transvaalensis* and would include the tool-using phase of the lineage involving small-brained forms which were primarily tool-using, had relatively poor communication and comparatively simple social structure. The second could be *H. sapiens*, including larger-brained tool-makers who possessed greatly improved means of communication and comparatively complex social structure. These two species would clearly intergrade but by the very nature of the situation in a single lineage it is not possible to have satisfactory division points for taxonomic purposes, once enough material is available, since there is genetic con-

tinuity between successive time levels throughout the sequence. In this event the whole lineage in which culture is a very important adaptive mechanism is included in a single genus and the two species defined in terms of two major stages of cultural development.

## PROGRESS OF CANCER RESEARCH

THE British Empire Cancer Campaign for Research in 1963 spent more than £1 million in support of cancer centres (40 in number) and individual research workers. The investigation described in the 1963 report of the Campaign\* can be divided into three main groups dealing with (1) biology of cancer (I. H.); (2) radiotherapy and the physics and physical chemistry of radiations (P. A.); (3) clinico-pathology of cancer (A. L. L.). Part I can be subdivided into five classes of investigation, namely, carcinogens and carcinogenesis, immunity in cancer, characteristics of tumours and tumour cells, cytogenetics and cancer viruses; and the two first-mentioned groups, carcinogenesis and immunology, by far attract most work in this field of research.

### Biology of Cancer

Passey and Elson at the Chester Beatty Institute find that the result of cigarette smoke is a deleterious effect on the weight at birth and growth rate of young rats the mothers of which had been subjected to daily breathing of cigarette smoke in a smoking cabinet before being mated (quite apart from the fact that the cigarette is the cause of four-fifths of all human lung cancer, which now kills 25,000 a year in Britain).

Brookes and Lawley, also at the Chester Beatty, have investigated the binding of <sup>14</sup>C- and <sup>3</sup>H-labelled hydrocarbons (four carcinogenic and two non-carcinogenic) to the nucleic acids of mouse skin and conclude that "these results suggest that reaction with DNA is the significant reaction required for carcinogenic activity, and are consistent with the mutation theory of carcinogenesis". (Brookes and Lawley do not go into such questions as—how to fit into this scheme carcinogens like plastic films (but not plastic powders), metal foils, cholesterol or radiations; why some chemical compounds are potent carcinogens for some species of animal and not for others, or even for some tissues of a particular experimental animal and not its other tissues.)

Case *et al.* have examined the incidence of occupational bladder tumours in industries such as rubber and cable making where the operatives may be exposed to the naphthylamines, benzidine or related compounds, carcinogenic to the bladder. Case states: "The rubber industry has never been the subject of an efficient epidemiological survey of bladder tumours because it has been generally assumed that adequate grounds exist for believing that all the dangerous compounds had been brought to light. This belief was strongly contested by the authors of the report (Case and Hosker, 1954). The only means of assessing whether or not any danger still persists is a rather indirect one based on death certificates and employment tables, with perhaps a little help from the number of new cases of bladder tumour coming to light within the industry itself". Case quotes the number of death certificates where tumour of the bladder was mentioned relating to workers in rubber occupations: the numbers were 20 and

27 for 1952–56 and 1957–61 compared with 9.8 and 11 to be expected if the incidence were the same as in England and Wales generally. He concludes that "a detailed epidemiological study of the situation with the full co-operation of the rubber industry and the trade unions concerned, would therefore seem to be eminently desirable".

Powell and Wright have been investigating chemical carcinogenesis *in vitro* using  $\beta$ -propiolactone on cultures of lung tissue from 15-day-old August rat embryos; after a somewhat lengthy description of the experiments it is concluded that the treated cells were "histologically indistinguishable from malignant epithelial cells *in vitro*", but Powell says nothing about assaying their malignancy by inoculating the cultures back into August rats. At the same laboratory (Mount Vernon Hospital) interesting investigations have been made of changes in the vitality of CBA mice; this strain is now showing a high neonatal mortality and the same change is reported from four other centres; some kind of infection to which the CBA are particularly susceptible might be implicated, but such an explanation would not account for the same change occurring in other laboratories.

At the Royal College of Surgeons the carcinogenic process in mouse skin is being investigated by an examination of the lysosomes, which are acid phosphatase organelles, in the cells of normal skin and in skin during exposure to carcinogenic agents.

At Cambridge, Glucksmann and Cherry have been working on microcarcinoma of the uterine cervix: writing on the malignant process in the cervix, they state: "It is now fairly widely accepted that most carcinomas of the uterine cervix pass through an *in situ* stage in which the cells have the morphological characteristics of malignancy but move to and are shed from the surface rather than invade the stroma through a defect in the basement membrane. The stage of microinvasion or microcarcinoma occurs between that of the *in situ* lesion and that of frank malignancy, and is characterized by the change in the direction of cellular movement towards and through the basement membrane".

"In microcarcinomas, tumour cells pass through the basement membrane into the stroma but undergo a process of differentiation in the form of either keratinization or mucification and are incapable of sustained growth." From experiments on the interaction of radiation and chemical carcinogen (dimethylbenzanthracene, DMBA) in the induction of cancer of the genital tract in castrate and normal female rats, these workers conclude that the action of radiation ( $6 \times 400$  r.) in the process of chemical carcinogenesis is of a hormonal rather than an immunological or mutagenic nature. Heath finds that some pure powdered metals suspended in serum are carcinogenic when injected into the muscles of rats (cobalt, cadmium, nickel): others were not (arsenic, zinc, tungsten, iron, tantalum, copper, beryllium and manganese). The process whereby tumours are induced consists first in a breakdown of the muscle fibres to free mononucleate myoblasts and, secondly, the transformation of the free myoblasts into malignant variants. Cobalt powder injected into mice caused as much necrosis as in rats but the muscle fibres regenerate in 6 weeks and tumours do not develop.

Pp. i–xxv; The Autonomous Councils of the Campaign, Pp. xxvii–xl. Part 2: The Scientific Report of the Researches undertaken by the Central Organization and its Autonomous Councils in the United Kingdom and by some of its Affiliated Organizations Overseas. Pp. 1–707. (London: British Empire Cancer Campaign for Research, 1963.)

Daniel has observed malignant transformation of fibroblasts from the foetal rat of a hooded strain which had been in culture for 4 years; these malignant fibroblasts give tumours when inoculated into hooded rats but are strain specific, for they will not grow in albino rats. The cultures show a wide range of degree of malignancy: some clones have given no tumours in 20 weeks on inoculation into rats, another gave 6 tumours in 8 animals in less than 4 weeks; other variants are sensitive to the presence of glucose in the nutrient. Daniel reports that continuous lines of mouse cells, unlike some lines of dog and hamster cells, lose Forssman antigens; by using antisera to the histocompatibility antigens A and K, some lines of cells in culture were shown (by being destroyed by antibody) to retain both antigens, but in another line 2-4 per cent of the cells had lost antigens and by culturing survivors the percentage rose to 18, and these remained viable after exposure to the antiserum-complement mixture.

Baldwin and colleagues, using the carcinogen *N*-hydroxy-4-acetyl-aminostilbene, find that it induces carcinoma of the ear duct in 85 per cent of rats tested; why this compound should select ear ducts for its site of action remains to be explained.

Baldwin has confirmed that "seven normal liver cell sap antigens and at least six microsomal antigens are deleted from DMAB-induced (aminoazo-dye) rat liver tumour" and that: "Further studies on the antigenic composition of the cell sap fraction from DMAB-induced rat liver tumour, utilizing rabbit antisera prepared against this fraction, have indicated the presence of a number of abnormal antigens which do not cross-react with normal liver cell sap. Moreover, these antigens do not cross-react with components in cell sap fractions from apparently healthy liver taken from tumour-bearing rats, indicating that they arose during tumour induction rather than as a non-specific response to carcinogen feeding. Precise identification of the number and nature of abnormal cell sap antigens in tumour is still incomplete but immunoelectrophoretic studies have demonstrated three major and four minor components.

"Comparison of the antigenic composition of liver cell sap fractions from rats after varying periods of DMAB feeding, utilizing anti-normal liver cell sap antiserum, has demonstrated that one of the normal liver cell sap antigens which did not cross-react with tumour was deleted as early as 30 days after carcinogen treatment. Similarly a normal liver microsomal antigen which was deleted from tumour could not be detected after 30 days DMAB feeding. In view of the finding that the initial 4-6 weeks of carcinogen feeding is a critical period in carcinogenesis (Arcos *et al.*, 1960) a more detailed assessment is being made of cell antigen changes during this time.

"Sera from rats during the earlier stages of carcinogenesis are now being examined for circulating tissue antigens. Although not yet completed, these studies have shown that tumour cell sap antigen was detectable in serum as early as 90 days after DMAB feeding. Clearly, therefore, the abnormal antigens detected in DMAB-induced tumour will become available during carcinogenesis for the induction of an immune response in the host. Whether an immune response is induced and its possible significance in carcinogenesis have still to be evaluated."

Orr *et al.* have investigated the effect of injecting small quantities of DMBA subcutaneously into new-born rats. Nearly half the animals developed tumours after one year; these were chiefly haemangiomas, some of them malignant, in the subcutaneous tissues, muscle, spleen and uterine horns. Bonser at Leeds has worked for many years on some compounds used in the dye and rubber industries where they are liable to induce bladder cancer in operatives: 2-naphthylamine when tested on dogs induced bladder tumours in every dog surviving administration of the compound for two or more years, the latent period being about five years. Peacock in Glasgow has

tested the anti-tuberculosis drug isoniazid on the lung tissue of rats, hamsters and desert rats: this compound, like urethane, is a potent carcinogen for the lung of the mouse; he finds that only the mouse and not the other three species develop lung tumours. Mice of the *C3Hf* strain have an incidence of more than 20 per cent of lung adenoma even when kept in a soot-free atmosphere; although many adenomas are found in lungs that also show chronic inflammatory lesions, tumours of about 1 mm diameter have also been found in apparently healthy lungs.

Peacock has tested asbestos injected into the air sacs of fowls. Two birds developed tumours, one of which involved the syrinx (bifurcation of trachea), the proventriculus, lungs and ovary; the second tumour had infiltrated the site of injection, humerus and lung. At the New Zealand centre in Otago, Bielschowsky has found that urethane, which is only mildly leukæmogenic for most strains of mice, produces thymomas in a third of treated mice of the *NZB* strain.

At the South African Institute, Oettlé has observed that his colony of mastomys (kangaroo rat), which is the only rodent liable to spontaneous gastric cancer, is now undergoing a decline in this form of neoplasia but remains extremely liable to papillomatosis of the skin, perineum and vagina which occasionally progresses into squamous carcinoma.

Weipers *et al.* at the Glasgow Veterinary School have reported on lymphosarcoma in domestic animals; a proportion of the animals in a cattle herd with the disease showed chromosomal aberrations in blood cultures of circulating lymphocytes; this form of cancer has also been observed in dogs (150 cases) and pigs and in the cat, where it could be transmitted experimentally, and electron microscopy showed virus-like particles 100 m $\mu$  in diameter which were very similar in structure to the viruses of murine leukæmias.

At the Chester Beatty Institute, Delorme, Mikulski and Alexander have investigated the treatment of tumours in rats by infusion of lymphocytes from a donor rat which had been immunized with grafts of tumour cells (benzpyrene-induced fibrosarcoma); some regression resulted in 70 per cent of animals and in 25 per cent the growth of tumour was delayed by more than 60 days. In another experiment  $2 \times 10^6$  antilymphoma lymphocytes from the spleen of a *CBA* mouse which had destroyed grafted lymphoma cells specific to *DBA/2* mice prevented the growth of  $10^4$  lymphoma cells inoculated into *DBA/2* mice which when untreated can succumb to tumour growing from a single injected lymphoma cell.

At Guy's Hospital, Tuffrey and James have shown that epitheliomas produced in *C57BL* mice with dimethyl-benzanthracene are antigenic within the strain of origin, and Wang (King's College Hospital) has found evidence of the partial loss of normal tissue antigens in human tumours, and indications of the presence of additional specific tumour antigens. Watkins has made a detailed investigation of the serum  $\gamma$ -globulin system of the mouse during immunization with tumour cells and extracts.

Smith at Leeds immunized *C57BL* mice with *A* strain mammary carcinoma, and suspensions of the lymph nodes were then injected in  $F_1$  hybrid mice (*A*  $\times$  *C57BL*) which next received a subcutaneous graft of the same *A* tumour; some inhibitions and failures to engraft were found, while 100 per cent of control grafts 'took'.

Ingleton has examined by diffusion technique the antigens of mouse liver and finds that, after only 48 hours' treatment with *O*-aminoazotoluene, two slow-moving components unique to mouse liver fractions are lost or masked.

Burch at the Radiotherapy Centre in Leeds has brought out a theory of carcinogenesis based on immunity which is a gem of its kind. He writes: "Many observations and certain theoretical considerations indicate that immune factors are important in carcinogenesis. In a theoretical analysis of the aetiology of human cancers (Burch,

1963a) it has been concluded that in the absence of viral or hormonal factors, both homologous structural genes at an autosomal locus need to be mutant before malignant conversion can occur. Several structural loci may be at risk, each with a similar phenotypic expression. When only one member of the homologous pair of structural genes is mutant, it appears that under certain conditions, hyperplasia but not malignancy can result.

"From a logical argument (based on autoimmune data) it is concluded that the target tissue antigen (or 'tissue coding factor'—TCF) in disturbed tolerance autoimmunity has the same polypeptide structure as the normal (pre-mutant) cell bound 'antibody'. Genotypic homozygosity at one (at least) of the two autosomal loci associated with the synthesis of cell bound 'antibodies' and TCF's appears to be a general prerequisite for the development of a pathological autoimmune reaction. This gives some support for the conclusion (Burch, 1963b) that in carcinogenesis the autoimmune transformation of a 'carcinogenic' into a malignant cell requires that homologous autosomal structural genes in the former cell must be both mutant."

Schild at University College, London, has investigated specific tumour antigens using anaphylactic tests; the complexities of this line of research can be appreciated from his statement: "It is apparent that positive anaphylactic tests with serum are obtainable with some tumours but not with others. Experiments are at present under way to determine whether, in the case of tumours which give a high percentage of positive results, similar positive results are obtained with non-malignant conditions, i.e., whether the response is specific for tumours or not".

Stuart in Edinburgh reports that he has "found it possible to prepare lymphoid cells which exert a direct action on the Landschütz tumour and have no effect whatsoever on normal host tissue (Stuart and El Hassan, 1964). Thus we now have an experimental model in which an immunological stimulus reacts specifically with a rapidly growing neoplasm and fails entirely to damage the host tissues".

### Radiotherapy and the Physics and Physical Chemistry of Radiations

As in previous years experiments involving ionizing radiations constitute a very substantial part of the research supported by the Campaign. Recent advances in radiobiology have opened the way to gaining an understanding of the biological basis of radiotherapy, surely the first step in the discovery of improvements in this method of treatment. The killing by X-rays *in vitro* can now be determined with precision and the field has been opened to the investigation of the role of host factors and physiological state on radiation response *in vivo*. Investigators at St. Bartholomew's Hospital have shown that skin reactions can only be explained if the behaviour of the cells *in vivo* is very different from that found *in vitro*. It is believed that these investigations may make it possible to determine an optimum fractionation régime which achieves the maximum differential between damage to tumour and normal tissue. The possible role of pharmacologically active factors released in the skin on irradiation is being examined in connexion with the same problem at the General Hospital, Northampton. The ability of different organs, containing rapidly dividing cells, to withstand continuous irradiation varies widely and indicates the complexity that is encountered when radiation is investigated at the tissue level. At the Physics Department of the Institute of Cancer Research, it was found that while the small intestine can maintain a steady state of cell population even when challenged continuously with  $\gamma$ -rays at a dose rate of 415 r./day, the growth of tumours was stopped by continuous irradiation at an intensity of 176 r./day. An immunological method of increasing the radiosensitivity of primary

chemically induced tumours has been developed at the Chester Beatty Research Institute. To eradicate a tumour it is not always necessary to kill (or sterilize) the last cell and in some cases radiotherapy may achieve a 'cure' by reducing the number of cancer cells to a small fraction which can then be eliminated by immunological processes. This is supported by the finding that no correlation could be found between the widely varying radiosensitivity of sarcoma cells *in vitro* and the *in vivo* response to X-rays of the tumour from which the cells were derived.

Much effort continues to be devoted to the factors which determine the sensitivity of isolated cells and to methods of modifying it. The problem is very complex, since the radiation-induced lesions can be restituted, often very effectively, by post-irradiation repair processes. If these are assisted or impaired the radiosensitivity can be greatly altered even when the nature of the primary radiation lesion is not affected. The sensitizing action of oxygen is well known and is believed to occur at the level of the initial radiochemical events. Workers at Mount Vernon Hospital investigated the possibility that this effect was due to the trapping by oxygen of radiation-produced hydrated electrons. If this were the case there should be no oxygen effect at low pH values. By using a sulphur bacillus capable of withstanding strong acid they were able to demonstrate pronounced sensitization by oxygen at pH 1, and this suggests that the hydrated electron is unlikely to play a major part in this system at least. The same workers have made an exhaustive investigation of the two most effective types of protective agents for bacteria, that is, aliphatic substances containing either SH or OH compounds. The key difference is that the SH substances are active at one-hundredth the concentration of those containing alcoholic groups. That there is a complex interplay of many factors in the determination of radiosensitivity is illustrated by nitric oxide, which can be made to sensitize or to protect micro-organisms depending entirely on the conditions used (Christie Hospital and Holt Radium Institute). At the Chester Beatty Research Institute it was shown that the greater radiosensitivity of mammalian cells and of bacteria grown in medium containing bromodesoxyuridine was largely due to the fact that post-irradiation repair was inhibited. Cells with little recuperative capacity were sensitized only to a very small extent.

Almost nothing is known about the nature of the repair processes which rescue a cell from a lesion that would otherwise have been fatal. The majority of chemical and biochemical work is concentrated on the nature of the primary radiation lesion. Our understanding of radiation chemistry is being advanced by the use of physical tools; electron spin resonance is being used at half a dozen centres to investigate the radicals formed when organic substances are exposed to radiation. The technique of flash photolysis used at the Christie Hospital in Manchester and at Mount Vernon Hospital is providing much information about the nature of the unstable species that are formed when aqueous solutions are irradiated. Chemists had speculated rather widely about the nature of radical intermediates in radiochemical reactions and many of these ideas can now be checked. Although the basic concepts of radiation chemistry have not been affected these new techniques have made it necessary to re-evaluate much of the finer detail. The implications of all this to radiobiology lie in the future; before the details of radiation chemistry can be considered the nature of the organelles within the cell that are critical for radiation damage have to be determined. Elegant experiments at the Strangeways Laboratories with microbeams of  $\alpha$ -particles have confirmed that mammalian cells *in vitro* are extremely resistant to irradiation when it is confined to the cytoplasm, and that part of the nucleus has to be included to achieve effective killing. Biochemical investigations also point to the nucleus, and in murine lymphoma

cells irradiation by a few hundred r. was shown to interfere within a few minutes with nuclear RNA (Chester Beatty Research Institute). However, the cytoplasm undoubtedly plays an important part in radiation injury, possibly because it is the site of a repair system which is itself radiosensitive. The lethal lesion may be in the nucleus, but whether it is restituted or not may depend on the integrity of structures in the cytoplasm. Workers at the Chester Beatty Research Institute concluded that in bacteria the site of action of some powerful radiosensitizers and radioprotectors appeared to be at or near the cell membrane. Damage immediately after irradiation of the DNA in cells, as measured by physico-chemical methods, was not altered by treatments which greatly varied the radiosensitivity in terms of lethality.

Radiation is a universal and most powerful carcinogenic and leukæmogenic agent. Without doubt, it promises to be a most valuable tool in the search for the causes of cancer. At St. Bartholomew's Hospital, lung cancers following whole-body irradiation have been examined in great detail. Those of aveolar origin are produced by relatively small amounts of irradiation and become less frequent as the dose is raised above 150 r. Thus in animals that have received 470 r. the incidence is considerably lower than in unirradiated controls. Tumours of bronchial origin are more rare, but their number increases at high doses. These results have been interpreted in terms of the radiosensitivity of cells once they have undergone the malignant transformation. Host factors cannot, however, be neglected, as is shown by the observation from the Strangeways Laboratory that radiation acts synergistically with carcinogenic hydrocarbons in inducing tumours of the genital tract of castrated rats, while for intact rats radiation reduces the incidence of chemically induced tumours.

### Clinico-pathology of Cancer

An example of the way in which expertise in a specialized field may aid an investigation in an apparently unrelated one is provided by Dent's group at University College Hospital. For nearly 20 years Dent has been a leading investigator of calcium and phosphorus metabolism, specializing in problems of renal dysfunction, parathyroid tumour, and vitamin D metabolism. He now reports that about 50 per cent of a group of patients suffering from superficial, uncomplicated squamous cell and basal cell carcinoma have a urinary calcium-level above the usually accepted limit of normality and about one-third have a low plasma phosphorus. The plasma calcium and plasma alkaline phosphatase are normal in all cases. These findings are unaltered after the tumour has been removed or treated by radiotherapy and it appears most likely that there is a metabolic predisposition to the development of skin cancer in these patients. The changes are similar to those of idiopathic hypercalciuria, but skin cancer patients, unlike idiopathic hypercalciurics, do not form renal stones. Nor is the formation of renal stones a feature of other hypercalciuric cancer patients, for example, those cases of cancer of the breast with widespread skeletal metastasis. A hypothesis that cancer patients possess a mechanism which protects them against the formation of renal stones is to be investigated: the results will be awaited with interest, since there is a great difference between the behaviour of a basal cell carcinoma, which may appear micro-anatomically as a slowly growing, locally destructive proliferating malformation of skin appendages, and the behaviour of the common mammary carcinoma, which is an anaplastic tumour. It would be interesting to know whether there were similar findings in patients with tumours which are comparable but not malignant, in patients with a tumour, at present benign, which has malignant potentialities, and so on. All manner of avenues for exploration are suggested, and there will be no shortage of material; the

bottleneck will be the time and staff required to extend these investigations.

Metabolic associations of consequences of malignancy are matters for which all workers in the cancer field should be on the *qui vive*. Many of the correlations so far recorded, for example, hypokalaemic alkalosis resulting from adrenal cortical hyperplasia in patients with carcinoma of the bronchus, diabetes mellitus and carcinoma of the body of the uterus, are difficult to explain using our present knowledge, but the patients invariably suffer metabolic disorders and investigations of these are almost certain to be fruitful.

A group of workers from the gas industry has been investigated for taste appreciation, colour blindness, right- and left-handedness, as well as the social background, in an attempt to discover whether there is a particular type of constitution which renders a man susceptible to tar warts or skin cancer.

As a result of careful trials, a group at the Royal Marsden Hospital has reported that chemotherapy (chlorambucil) has a definite part to play in the treatment of advanced ovarian adenocarcinoma. A regression was found in 60 per cent of patients treated with alkylating agents. This is a good example of empiricism in medicine, for at present it appears to be pure chance whether or not an 'irremovable' adenocarcinoma responds to irradiation, radiomimetic drugs or alkylating agents. Clinical behaviour and pathology are not useful guides and those conducting the trials, provided as they are with quite hopeless advanced cases of disease, cannot be selective until they have gained sufficient experience in the management of a group of cases. This will come rapidly with, for example, carcinoma of the bronchus, where 10-20 patients may be gathered in a few weeks, but in the case of the sarcomata, which are all relatively rare, experience in the use of drugs is hard to come by.

No significant advances in the techniques or results of regional perfusion with chemotherapeutic agents are recorded.

There is once again a first-class lesson in tumour pathology from St. Mark's Hospital, in which benign and malignant epithelial tumours of the large intestine are discussed. Each year the report from St. Mark's Hospital exemplifies the very best of scientific tradition—the painstaking, meticulous collection of data, their rearrangement, and the thought processes leading to conclusions. The methods are essentially those of surgical pathology—methods which have not significantly changed in forty years, but which continue to provide fundamental contributions to knowledge.

Nephroblastoma (Wilm's tumour) arises before the age of eight, and usually before the fourth year. Twenty-five years ago the prognosis was that 10 per cent would survive two years or more with a variety of treatments. The Children's Hospital (Great Ormond Street) between 1952 and 1960 has achieved a 47.5 per cent survival rate using a standard procedure. This consists of immediate nephrectomy by a route which permits early ligation of the renal blood vessels (to forestall dislodgement of the tumour into the blood stream as a result of manipulating the organ) followed by X-irradiation.

Gluckmann at the Strangeways Laboratories continues his clinico-pathological investigations of human carcinoma of the cervix in an attempt to avoid the blunderbuss irradiation methods at present employed, and substitute a more critical approach based on the known response of the individual tumour to an initial dose of irradiation as seen in serial biopsies. (In this context the term 'human' is really redundant since carcinoma of the cervix is virtually unknown in other species.) Those showing a favourable response were treated by radiotherapy only, and those showing an unfavourable response by radiotherapy followed by surgery.

Inevitably much of the clinical survey work is concerned with the frequent, lethal tumours. The Marie

Curie Hospital surveys its results in the management of carcinoma of the uterine cervix treated by a variety of combinations of surgery and irradiation; unfortunately the presentation is far from clear.

Bloch has shown that under mild hypothermia (30°–33° C) in men there is an increase in sensitivity of cerebral tissue to irradiation, that tumour tissue shows a relatively greater sensitivity than normal brain tissue but that life is not prolonged by adding hypothermia to irradiation in the management of brain tumours (to which can be added the fact that the results of treatment of the gliomata—primary malignant tumours arising in brain from neuroglia—except in the relatively uncommon type which can be removed surgically at the expense of a cerebellar hemisphere—are very poor).

St. George's Hospital provides a very detailed review of tumours arising from the acoustic (8th cranial) nerve. These are histologically benign tumours of the nerve sheath cells and in general are called 'neurilemmomas' or 'schwannoma'. Such tumours can affect any nerve in the body, but the 8th nerve is a site of predilection. Although this tumour is histologically benign, it has been held responsible for the death of 107 of a series of 280 cases in which it was known to be present. The tumour occurs in a notoriously inaccessible site within the skull, is hazardous to remove and virtually radioresistant.

## OBITUARIES

### Prof. V. A. Bailey

It may be said that Prof. Victor Albert Bailey, who died on December 7, 1964, was one of a decreasing number of physicists who lived and worked through what is now thought of as the 'heroic era' in physics.

He had the good fortune to be associated at an early age of his life with Sir John Townsend and his school in Oxford. Townsend soon discovered in his young associate a remarkable combination of mathematical facility and experimental skill. Much of the classical work on the electrical breakdown of gases was published conjointly by Townsend and Bailey.

When he accepted a chair of physics in the University of Sydney in 1924 (in 1936 this became the chair of experimental physics), Bailey immediately established a research school engaged in the elucidation of various phenomena occurring in ionized gases and other ionized media such as the upper atmosphere. Although a large number of publications arose from this work, Prof. Bailey will probably be best remembered for the elucidation of an effect observed by early wireless operators and sometimes referred to as the 'Luxemburg effect'. Briefly, it was observed that the station *Radio Luxemburg* could also be received on neighbouring frequencies but only under certain rather puzzling conditions. Bailey showed by theoretical calculations and experiments that radio waves can interfere with each other when passing through a medium such as the ionosphere, that is, they can impress their modulation eventually on to each other. In addition he showed that the effect would be considerably increased if the 'disturbing' transmitter should happen to be tuned to the so-called 'gyro-frequency' which depends on the strength of the Earth's magnetic field at the point of interference of the two waves. This gyro-magnetic resonance has long since been confirmed experimentally and developed into a standard method of investigating the properties of the ionosphere.

During the Second World War the Australian Government entrusted Prof. Bailey with the task of forming, within the University of Sydney, a school of basic scientific instruction in radar techniques for officers of the Australian armed forces. From this school several hundred graduates emerged, some of them taking regular science courses after the War. This shows that at that stage Prof. Bailey's scientific reputation was already looked on as unquestionable.

After the War he returned again to the subject of wave propagation in ionized media, taking into account more and more of the numerous variables involved in these modes of propagation, such as the relativistic motion of the charge carriers. Some of this work is considered classical in the field that is now called 'plasma physics'.

After his retirement in 1960, Prof. Bailey turned his attention to cosmology and in particular investigated the

possibility that some of the celestial bodies such as the Sun may carry permanent electrical charges of considerable magnitude. He read three papers on the subject just recently at the Galileo celebration convention in Rome. He intended to continue this work, and in fact had accepted the offer of a visiting professorship in the Department of Space Science and Applied Physics of the Catholic University of America, in Washington, D.C., for February 1965.

His death will be mourned by the great number of his colleagues, students and friends all over the world.

KURT LANDECKER

### Prof. Umberto D'Ancona

It is with very great regret that biologists learnt of the sudden death of Prof. Umberto D'Ancona on August 24. Only in the previous month he had been taking active and far-sighted part at the meeting of the International Union of Biological Sciences at Prague, and at the subsequent meeting on the International Biological Programme at Paris, where his wisdom and wide biological outlook seemed destined to exert an important influence on the future development of that Programme.

He was an outstanding example of that handful of biologists who carried and adapted the traditions of nineteenth-century evolutionary biology to the wider and very different outlook of to-day.

Born in Fiume on May 9, 1896, he first studied science at the University of Budapest. Afterwards he became an Italian citizen and transferred to the University of Rome, where in due course he became an assistant in the Institute of Comparative Anatomy under Prof. Grassi and Prof. Cotronei. From 1929 until 1936 he held the chair of zoology at Siena and then for a brief spell at Pisa. Since 1937 he has been professor of zoology at Padova and director of the Institute of Zoology.

D'Ancona took a full share in the administrative responsibilities of his University. But his enduring interest was in limnology and marine biology. The Hydrobiological Station at Chioggia was founded and directed by him, and also the Istituto Nazionale di Studi Talassografici at Venice, and he was a governor of the Marine Biological Institute of the Adriatic. In the end he was a man naturally called on by international authorities to further limnological and marine biological science. He was president of the Limnological Section of the International Union of Biological Sciences, and recently played a major part in initiating the international programme of productivity in relation to the sardine fisheries of the Mediterranean-Biscay-Channel area.

His researches were recorded in some 250 valuable papers and books. These illustrate clearly the development and expansion of his ideas. He gained a rigorous training in cytology and histology, the embryology of

fish, and by his work on sex-determination and differentiation in fish. He would turn to systematics in his work on the amphipod *Niphargus* as well as to the biology and systematics of fish, particularly of sturgeons and of eels; and these widening interests led him into his researches in hydrobiology and oceanography, and to his book *The Struggle for Existence*, well known in both the Italian original and its English translation.

He received many well-deserved honours both in his own country and in others. He was awarded the National

Prize of the Accademia dei Lincei in 1955 and the Médaille Memorial of the Fondation Albert 1<sup>er</sup> Prince de Monaco. Only last year he received the Manley Bondell Prize.

Learned and kindly, he saw what should be done and how to get things done, and how to promote international goodwill and co-operation to extend our knowledge of Nature. We offer our sympathy to his wife, herself a distinguished zoologist and his collaborator, and to his daughter, a pathologist in the University of Padova.

C. F. A. PANTIN

## NEWS and VIEWS

### Chief Scientist of the Army Department:

Mr. E. C. Cornford

MR. E. C. CORNFORD has been appointed chief scientist of the Army Department in succession to Dr. W. Cawood, who has been appointed chief scientist of the Ministry of Aviation (*Nature*, 204, 923; 1964). Mr. Cornford graduated in mathematics at the University of Cambridge in 1938 and in the same year entered the Ministry of Supply. In 1945 he joined the Guided Weapons Department of the Royal Aircraft Establishment and stayed there until 1951. During this period he was concerned not only with guided weapons development but also with weapons research, air warfare and radar aids to navigation. From 1951 until 1954 Mr. Cornford served on the Staff of the Scientific Adviser to the Air Ministry. He then rejoined the Royal Aircraft Establishment, eventually to become the head of the Guided Weapons Department. In 1961 he joined the Ministry of Defence as chairman of the Defence Research Policy Staff. Since then he has been assistant chief scientific adviser (projects) at the Ministry of Defence. Mr. Cornford took up his new appointment on January 1.

### Department of Genetics in the University of Leeds

A DEPARTMENT OF GENETICS has been established in the Faculty of Science of the University of Leeds. The new Department will be closely associated with the other biological departments in a School of Biological Sciences, a new building for which is at present being planned. It will be responsible for the elementary and advanced teaching of genetics both to specialists and to students from other departments, and the members will undertake, supervise and promote research in the subject, and co-operate with other departments in which research in genetical topics is already being undertaken.

Prof. J. R. S. Fincham

DR. J. R. S. FINCHAM, head of the Department of Genetics at the John Innes Institute, has been appointed to the chair of genetics and the headship of the new Department of Genetics in the University of Leeds. Dr. Fincham was educated at Hertford Grammar School and Peterhouse, Cambridge, where he read the Natural Sciences Tripos and gained first-class honours in Parts I and II. He was awarded an Agricultural Research Council research studentship in 1946 and spent two years in the School of Botany, Cambridge, followed by one year at the California Institute of Technology. During 1949-50 he was a Bye Fellow of Peterhouse and in 1950 he was awarded the degree of Doctor of Philosophy for his dissertation on "Genetic and Biochemical Studies on *Neurospora*". Dr. Fincham joined the staff of the Department of Botany at University College (later the University of) Leicester as lecturer in 1950 and was appointed to a readership in genetics in 1954. He has held his present post as head of the Department of Genetics at the John

Innes Institute, Bayfordbury, Hertford, since 1960. He spent the academic year 1960-61 as visiting associate professor of genetics at the Massachusetts Institute of Technology. In 1964, Dr. Fincham was awarded an Sc.D. degree of the University of Cambridge. His main research interests are in the field of microbial and molecular genetics and will complement work already in progress in the biological sciences in the University under the direction of Prof. R. D. Preston in the Astbury Department of Biophysics, and Prof. F. C. Happold in the Department of Biochemistry.

### U.S. National Academy of Engineers

A NATIONAL ACADEMY OF ENGINEERING has been formed under the charter of the U.S. National Academy of Sciences. Acting under the authority granted by its Congressional Act of Incorporation of 1863, the National Academy of Sciences has approved Articles of Organization which bring the National Academy of Engineering into being as part of its own structure, operating on an autonomous and parallel, but co-ordinated, basis. The new Academy will share in the responsibility of the National Academy of Sciences of advising the Federal Government, on request, in all areas of science and engineering.

The adoption by the National Academy of Sciences of the Articles of Organization of the National Academy of Engineering brings to a climax the discussions which began in 1960 when the Engineers Joint Council, in co-operation with the Engineering Foundation and the Engineers Council for Professional Development, and with representatives from the National Academy of Sciences and the National Research Council, appointed a committee to make an intensive examination of the need and feasibility of an engineering academy. The President of the National Academy of Sciences will sit *ex officio* on the Council of the National Academy of Engineering, and the National Academy of Engineering will, in turn, have *ex officio* representation on the Governing Board of the Academy-Research Council. Concerning membership of the National Academy of Engineering, the Articles of Organization state that, in addition to the primary qualifications of important contributions to engineering theory and practice or unusual accomplishment in technology: "A candidate for membership shall be recognized by his associates and others for his professional integrity, as well as for his engineering accomplishments. Effectiveness and efficiency in leadership of organizations that have conducted pioneering or complex programs, have made noteworthy contributions to the field of engineering education, should be weighed as supplementing the primary qualifications . . ."

### Aims and Objectives

THE aims and objectives of the National Academy of Engineering, as formulated by the committee appointed by Dr. F. Seitz and set forth in the Articles of Organization

for the National Academy of Engineering, are: (1) To provide means of assessing the constantly changing needs of the United States and the technical resources that can and should be applied to them; to sponsor programmes aimed at meeting these needs; and to encourage such engineering research as may be advisable in the national interest. (2) To explore means for promoting co-operation in engineering in the United States and elsewhere, with the view of securing concentration on problems significant to society and encouraging research and development aimed at meeting them. (3) To advise the Congress and the executive branch of the Government, whenever called on by any department or agency thereof, on matters of national import pertinent to engineering. (4) To co-operate with the National Academy of Sciences on matters involving both science and engineering. (5) To serve the nation in other respects in connexion with significant problems in engineering and technology. (6) To recognize outstanding contributions to the nation by leading engineers.

#### Officers

At a meeting held on December 10, by-laws were adopted and the following officers were elected: *President*, Dr. A. B. Kinzel, vice-president (research), Union Carbide Corporation; *Vice-President*, Dr. E. A. Walker, president, Pennsylvania State University; *Secretary*, Dr. H. Work, director of the Research Division and Associate Dean, School of Engineering and Science, New York University; *Treasurer*, Dr. T. C. Kavanagh, Praeger-Kavanagh-Waterbury, Engineers-Architects. The founding membership of the National Academy of Engineering has been formed from a committee of twenty-five appointed by Dr. F. Seitz, president of the U.S. National Academy of Sciences (see *Nature*, 202, 750; 1964), on nomination by the Engineers Joint Council to deal with the primary organizational tasks of the new Academy.

#### Charter Members

THE twenty-five charter members of the National Academy of Engineering are: H. W. Bode, vice-president, Bell Telephone Laboratories, Inc.; Walker L. Cisler, chairman of the Board, Detroit Edison Co.; Hugh L. Dryden, deputy administrator, National Aeronautics and Space Administration; Elmer W. Engstrom, president, Radio Corporation of America; William L. Everitt, dean, College of Engineering, University of Illinois; Antoine M. Gaudin, Richards professor of mineral engineering, Massachusetts Institute of Technology; Michael L. Haider, president, Standard Oil Co. of New Jersey; George E. Holbrook, vice-president, E. I. du Pont de Nemours and Co., Inc.; J. Herbert Holloman, jun., Assistant Secretary of Commerce for Science and Technology; Thomas C. Kavanagh, Praeger-Kavanagh-Waterbury, Engineers-Architects; Augustus B. Kinzel, vice-president (research), Union Carbide Corporation; James N. Landis, vice-president, Bechtel Corporation; Clarence H. Linder, former vice-president and group executive, General Electric Co.; Clark B. Millikan, professor of aeronautics, California Institute of Technology; Nathan M. Newmark, head, Civil Engineering Department, University of Illinois; W. H. Pickering, director, Jet Propulsion Laboratory, California Institute of Technology; Simon Ramo, executive vice-president, Thompson Ramo Wooldridge, Inc.; Arthur E. Raymond, consultant, RAND Corporation; Thomas K. Sherwood, professor of chemical engineering, Massachusetts Institute of Technology; J. A. Stratton, president, Massachusetts Institute of Technology; C. G. Suits, vice-president and director of research, General Electric Co.; F. E. Terman, provost and vice-president, Stanford University; Charles Allen Thomas, chairman of the Board, Monsanto Chemical Co.; Eric A. Walker, president, Pennsylvania State University; and Ernst Weber, president, Polytechnic Institute of Brooklyn.

#### Part-time Course in Chemical Engineering in Britain

NOTWITHSTANDING the present-day shift in emphasis towards full-time education for all capable of being educated, the part-time course, which is a tradition in the technological ways of life in Britain, continues to flourish. In 1962-63, for example, there were 108,000 advanced students taking part-time courses, 53,000 in the day and 55,000 in the evening, as compared with 43,000 full-time advanced students in institutions of further education. More than ten years have elapsed since the Institution of Chemical Engineers first published its *Scheme for a Part-time Course in Chemical Engineering*. The purpose of that publication was to encourage the establishment of Higher National Certificate courses in chemical engineering, and a number of such part-time courses have since been in successful operation. The Institution (in co-operation with the Joint Committee for Higher National Certificate in Chemical Engineering in England and Wales) has now published a completely revised scheme designed for the boy or girl leaving school who wishes to become a chemical engineer by means of part-time study (Pp. 20. London: The Institution of Chemical Engineers, 1964). The student who completes the course for the Higher National Certificate will be considered in future to have qualified academically as a chemical engineering technician. The more ambitious student can proceed, through the endorsement course and Part 3 (Design Problem) of the Institution examination, to become a fully qualified professional chemical engineer, provided he or she can satisfy the experience requirements for corporate membership of the Institution. Copies of the scheme can be obtained free of charge from the Institution of Chemical Engineers, 16 Belgrave Square, London, S.W.1.

#### The Future of the National Parks

THE *Report and News Letter of the Friends of the Lake District* for August 1964, to which are appended the full text of the pamphlet *Traffic in the Lake District* (see *Nature*, 204, 508; 1964) and the statement on the report on future water resources made to the Manchester Corporation by their engineering consultants and issued in April 1964, makes some comments on the future of the National Parks in general (Pp. 21. Ulverston: Friends of the Lake District, 1964). It is urged that any attempt to cater for the more gregarious forms of recreation in National Parks must run counter to their essential character and function, and provisions for such forms of recreation should be made elsewhere. Attention is also directed to the way in which the new large-scale agricultural development also clashes with its surroundings and calls for much more effective control for agricultural buildings than exists at present. On water supply it is urged that the only real protection for the Lake District against further extraction lies in the development of alternative sources of supply and points out that in future the costs of desalinated sea-water are likely to match those of fresh water very closely. (See also p. 113 of this issue of *Nature*.)

#### Scottish Wildlife Trust

THE Scottish Wildlife Trust has recently been established to help to secure conservation in Scotland. The chairman is Sir Charles Connell. The new Trust will act as a co-ordinating body and will endeavour to do on a smaller scale what the Nature Conservancy is doing on a national scale. One of its functions will be to establish wildlife reserves on a small scale throughout Scotland. There are many places in Scotland where particular species occupy a restricted habitat, always in danger of being lost through ignorance or carelessness. There are also areas of special interest, particularly cliffs and forests, which the Trust hopes to protect from exploitation inimical to the maintenance of an attractive countryside and the conservation of its flora and fauna. Further information

and terms of membership can be obtained from the Secretary at 21 Regent Terrace, Edinburgh 7.

### Mutation Research; a New Journal of Genetics

THE increase in the bulk, and in the specialization, of research in the field of genetics is reflected in the appearance of another new journal, *Mutation Research*, an international journal on mutagenesis, chromosome breakage and related subjects (Amsterdam: Elsevier Publishing Co.). The editor is Prof. F. H. Sobels, of the University of Leiden, assisted by a large international editorial board which includes most of the active workers in this field. The first issue, dated May 1964, contains 10 major papers ranging from viruses to mice and generally of a high standard; the first paper, most appropriately, is by H. J. Muller whose fundamental discovery, in 1927, of the mutagenic action of X-rays inaugurated the whole field of mutation research. The volume will comprise approximately 600 pages; the annual subscription is £6 10s.

### Reproduction of Mammals

THE Eighth Oliver Bird Lecture given in London on November 23 by Dr. Alan F. Guttmacher, on intra-uterine devices used to control human fertility, was followed by a three-day international symposium on the "Comparative Biology of Reproduction in Mammals", held at the Zoological Society of London. The symposium was organized jointly by the Zoological Society and the Society for the Study of Fertility, and supported financially by the World Health Organization. A large proportion of the twenty-eight invited speakers came from overseas and included many distinguished biologists from the United States, the Commonwealth countries and Europe. Some of the topics were of a general nature, such as the evolutionary trends in the physiology of reproduction and the factors controlling the gestation period. The majority of the papers, however, dealt with particular aspects of the reproductive process in the male or female of a particular species or group of mammals. A complete session, at which five papers were read, was devoted to the consideration of reproduction in marsupials. To make the proceedings of the symposium available as soon as possible to all interested workers, abstracts of the papers will be published in the *Journal of Reproduction and Fertility* in the early part of this year and the full papers will appear later in the *Symposia of the Zoological Society of London*. Midway through the programme the overseas speakers visited the newly established Wellcome Institute of Comparative Physiology in Regent's Park. At its conclusion, Dr. Carl G. Hartman was presented with the first Marshall Medal of the Society for the Study of Fertility, by its chairman, Prof. A. S. Parkes. Looking back on these meetings, one was struck not only by the great volume of work that is being done on this subject at the present time, but by the enormous amount that is still to be learned before anything like a fully comprehensive picture can be presented. Dr. Guttmacher's lecture underlined the problems of population control, and the symposium did much to reveal the potential value of comparative studies in the regulation of the reproductive process of mammals.

### Radiation Preservation of Foods

IN Russia and Canada, potatoes are already being irradiated for commercial purposes and, following the recent Ministry statement on the subject, it is quite possible that food preservation by irradiation may begin in Britain very soon. Those interested in radiation preservation of food should read the report *Radiation Preservation of Foodstuffs* (Second Scandinavian Meeting on Food Preservation by Ionizing Radiation, Stockholm, September 9-11, 1963. Arranged by the Royal Swedish Academy of Engineering Sciences. Edited by Per-Olof Kinell and Vera Runnström-Roio. IVA Meddelande Nr.

138. Pp. 87. Stockholm: Ingeniörsvetenskapsakademien, 1964, 25 kr.). Five of the papers in the report are concerned with irradiation facilities, source strength, dose measurement, and dose distribution. The electron linear accelerator at Risø, Denmark, has been operated since 1961 for the industrial radiation sterilization of disposal surgical supplies at the rate of about six tons a month. In conventional heat treatment of canned foods the centre of the can must, of necessity, receive less severe heat treatment than the periphery. This problem can be overcome to some extent with radiation treatment by irradiating the cans from both ends.

One of the chief problems after sprout inhibiting or radurization doses is the recontamination of the food with micro-organisms. This increased susceptibility to storage rot is due either to: (1) tissue damage facilitating the access of micro-organisms; (2) residual radiation-resistant organisms now deprived of competitors; or (3) a combination of (1) and (2). Radiation can affect the wound healing mechanisms of plants to such an extent that flora which are normally harmless can become an important cause of storage rot. After irradiation, therefore, foods must be stored under refrigeration as close as possible to 0° C. *Aureobasidium pullulans*, also known as *Pullularia pullulans* or black yeast, is a very widely distributed fungus which is known to cause damage to wounded soft fruits in the United States. This organism has been shown to be very radiation resistant. The report also discusses the irradiation of fruit juices. The best method of preservation appeared to be irradiation with 0.5 Mrad, storage for a day at room temperature, and then heat treatment at 50° C. The yeasts were severely attacked both by the radiation and the heat treatment. When semi-preserved fish (tidbits) were irradiated, it was found that 300 krad was the highest acceptable dose from an organoleptic point of view.

There is a description of the use of ultra-violet radiation in the food industry, especially for meat storage when it is used to prevent the growth of psychrophilic bacteria. By irradiating either crystalline or dissolved D-glucose with 10 Mrad a substance toxic to *Pseudomonas* has been produced.

### Research in Mental Health

THE Schizophrenia Research Fund has been established to support research into problems connected with mental illness in general and schizophrenia in particular. The fund is administered by a Board of Trustees, and Mr. L. Kelly (Schizophrenia Research Fund, City Gate House, Finsbury Square) is acting as secretary. Initial impetus has been given to the fund by a gift of £50,000 from the Rothschild family, and the establishment of a Schizophrenia Research Fellowship, to which Dr. D. Straughan has been appointed. Dr. Straughan, who is at present at the Institute of Animal Physiology, Babraham, Cambridge, will work in the Department of Psychological Medicine in the University of Edinburgh. The fund will provide greater security of tenure than has hitherto been possible in research in this field, and Dr. Straughan's initial contract is for seven years. His work at Babraham has been concerned with pharmacological aspects of mammalian brain physiology, and he will concentrate on the biochemical basis of schizophrenia. It is hoped that this initial effort will attract interest in, and support for, work in the immense field of research bearing on the problems of mental health.

### The Royal Society and Nuffield Commonwealth Bursaries Scheme

AWARDS under the Royal Society and Nuffield Foundation Commonwealth Bursaries Scheme have been made as follows: Dr. S. I. Ali, lecturer in botany, University of Karachi, to enable him to study taxonomic problems of Leguminosae of West Pakistan at Kew and the British

Museum (Natural History); Dr. R. G. R. Bacon, reader in organic chemistry, Queen's University, Belfast, to assist him to gain information on the application of new instrumental methods, particularly nuclear magnetic resonance and mass spectrometry, to the study of complex products from organic oxidation-reduction reactions, at Melbourne; Dr. A. J. Cawley, associate professor, division of small animal medicine and surgery, Ontario Veterinary College, to enable him to learn research techniques in the study of bone and bone diseases of both man and animals, at Bristol and Oxford; Prof. I. M. Goodbody, professor of zoology, University of the West Indies, to enable him to visit British Columbia from April to June 1965, to extend his knowledge of living ascidians (Tunicata) and their ecology by a study of Pacific coast species, and with particular reference to the ecology of closely related species; Dr. Janet E. Harker, university lecturer in zoology, Cambridge, to enable her to extend her studies on malignant cell proliferation, caused by upsetting the time-control of endocrine secretion, by working on the relationship between this phenomenon and the time-control of regeneration, at the University of New England, Armidale; Dr. H. H. Huang, lecturer in physical chemistry, University of Singapore, to enable him to study the apparatus and techniques used in the field of the Kerr effect, at Sydney; Dr. R. Kretz, senior lecturer in geology, University of Queensland, to enable him to obtain data on the diffusion of alkali elements in silicate crystals and especially in natural aggregates of silicate crystals, to elucidate the kinetics of mass transfer and solid-state reactions in metamorphic rocks, at the Imperial College of Science and Technology, London; Dr. A. Lazenby, university lecturer in agricultural botany, Cambridge, to assist him to study some problems in techniques in selection criteria in grass-breeding; Dr. A. W. J. Lykke, lecturer in pathology, University of Adelaide, to assist him to study experimental techniques applied to the study of inflammation, at St. Bartholomew's Hospital Medical School, London; Dr. Enid A. C. MacRobbie, university demonstrator in botany, Cambridge, to enable her to visit Australia and to work, at Adelaide, on light effects on ion transport in *Nitella* and to learn the techniques used there in the study of ion transport in plant mitochondria; Dr. D. C. T. Pei, assistant professor of chemical engineering, University of Waterloo, Ontario, to enable him to spend about one year, commencing May 1965, with the applied heat group at the Imperial College of Science and Technology, London; Dr. C. R. Twidale, senior lecturer in geography, University of Adelaide, to assist him to study the weathering and landforms of the granite areas of south-western England, at Exeter.

### Mass Spectroscopy

A MASS SPECTROSCOPY GROUP has been set up for the principal purpose of arranging regular open meetings on the subject. The committee consists of: Dr. J. H. Beynon (Imperial Chemical Industries, Ltd., Manchester) (chairman); Dr. J. Cuthbert (United Kingdom Atomic Energy Authority, Harwell); Prof. A. Maccoll (University College, London); Prof. W. C. Price (King's College, London); Dr. J. D. Waldron (Associated Electrical Industries, Ltd., Manchester); R. M. Elliott (Associated Electrical Industries, Ltd., Urmston) (secretary). A meeting organized by the Group will be held at University College, London, during September 21-22. The meeting will be open to all and will cover all aspects of mass spectroscopy. Those interested are invited to submit titles of short papers on present work before February 26. The Committee will also be grateful to receive suggestions for topics of special interest which might be given prominence or generally discussed at the meeting. Further information can be obtained from the secretary, R. M. Elliott, Associated Electrical Industries, Ltd., Scientific Apparatus Department, Barton Dock Road, Urmston, Lancs.

### Churchill College, Cambridge :

#### Junior Research Fellowships

CHURCHILL COLLEGE offers at least three junior research fellowships in arts, mathematics, science or engineering. Applicants must be under the age of thirty on July 1, 1965, and not have spent more than four years in research work by that date. Candidates should apply to the Senior Tutor, Churchill College, Cambridge, for an application form, which must be returned by February 1, or submit a copy of a thesis by March 1. The junior research fellowships are for an initial period of three years and are of the value of £750 a year. An accommodation allowance of £250 and a children's allowance of £100 for each child are also paid to Fellows not resident in College.

#### Gulbenkian Fellowship

THE College also offers a Gulbenkian Fellowship which is open to graduates of any university other than those in the United Kingdom who wish to carry out advanced work, and is of the same value as the junior research fellowships. The tenure is normally for one year but may be extended. Applicants must be under the age of thirty on July 1, 1965, and not have spent more than four years in research work by that date. Applications should be submitted in the same way as for junior research fellowships.

### Announcements

PROF. JONATHAN W. UHR, director of the Irvington House Institute for Rheumatic Fever and Allied Diseases, and associate professor of medicine, New York University School of Medicine, was awarded on December 28 the Newcomb Cleveland Prize, the senior award of the American Association for the Advancement of Science, for his paper entitled "The Heterogeneity of the Immune Response". The prize, including an award of 1,000 dollars and a medal, is awarded annually for an outstanding scientific contribution to the author of a paper given at the previous year's meeting of the American Association for the Advancement of Science.

THE Pacific Science Center announces the institution of the Arches of Science Award, made possible through the financial support of the Pacific Northwest Bell Telephone Co., and consisting of a gold medal and a cash prize of 25,000 dollars. It will be awarded in 1965 to a citizen or a resident of the United States in recognition of "outstanding contributions to the better understanding of the meaning of science to contemporary man". Further information may be obtained from Pacific Science Center, Inc., 200, 2nd Avenue N., Seattle, Washington 98109.

THE sixth International Soil Mechanics Conference will be held in Montreal during September 8-15. Further information can be obtained from the secretary of the Organizing Committee, M. K. Ward, c/o National Research Council, Ottawa 2.

THE eighth European Congress on Molecular Spectroscopy will be held in Copenhagen during August 14-20. Further information can be obtained from H. C. Ørsted Institute, Chemical Laboratory Five, 5 University Park, Copenhagen Ø.

THE annual symposium on "Molecular Structure and Spectroscopy" will be held in the Ohio State University, Columbus, during June 14-18. Further information can be obtained from Prof. K. Narahari Rao, Molecular Spectroscopy Symposium, Department of Physics, Ohio State University, 174 West 18th Avenue, Columbus.

AN international conference on "Electron Diffraction and the Nature of Defects in Crystals" will be held in Melbourne during August 16-21. Further information can be obtained from Dr. R. I. Garrod, Aeronautical Research Laboratories, Box 4331, G.P.O., Melbourne, Victoria.

## THE ORDNANCE SURVEY

"I AM told," said Robert Louis Stevenson, "that there are people who do not care for maps, and I find it hard to believe." As if in substantiation of his belief, the Ordnance Survey during 1963-64 printed no less than 4 million maps and issued 3 million for sale, the highest total ever in one period of twelve months. Of these, the incomparably popular *One Inch to One Mile Series* accounted for almost half, the *Quarter Inch Series* for another quarter. In all, there are now just less than 100,000 different present-day sheets on all scales, and most of the small-scale series (one inch and smaller) are complete. The bulk of the outstanding programme comprises the 1:1,250 and 1:2,500 plan series, each of which is being produced at an annual rate of several thousand sheets, though so vast is their coverage that 150,000 are still needed. Moreover, the extent and rapidity of new building, motorway construction and other developments over the changing face of Britain necessitate a perpetual programme of revision, according to a careful scheme of priorities. This new material is sometimes required so urgently by public users that the Ordnance Survey makes it available through its Advance Revision Information Service.

Apart from this steady long-term progress, 1963-4 saw the appearance of a number of individual sheets of special interest. These include the beautiful map of Hadrian's Wall, plotted on a modern topographical base-map on a two inches to a mile scale, and a composite sheet of the Isles of Scilly on the 1:25,000 scale. A two-sheet edition of a *Route Planning Map*, in six colours, on a scale of 10 miles to an inch, has proved to be of such value to road-users, with its wide range of supplementary information, that it has already been reprinted three times since its first appearance in January 1964. New editions of the attractive *Tourist Maps* of the Lake District, the North York Moors and the Peak District have appeared, joined by a new recently published Cairngorms sheet which reflects the growing popularity of this mountain group as a ski-ing and climbing area. Preliminary work has been carried out on a proposed tourist map of the Cambridge district.

All this has been accomplished by a total personnel of only 4,500, whose headquarters in the near future will be the fine building under construction in Southampton. The Ordnance Survey first came to that town in 1841, following a fire in the Tower of London which had

destroyed its premises. A century later, though Southampton still remained the centre of the drawing and printing activities of the Ordnance Survey, the administrative headquarters were transferred to Chessington in Surrey. When the new building is completed, the disadvantages of scattered and inadequate accommodation will be overcome, and the Ordnance Survey will have returned home.

The accomplishment of so much with such a relatively small personnel has been practicable only by the constant introduction of technological improvements: the extension of aerial photography (though badly hindered in 1963-64 by long periods of poor flying weather), the acquisition of new stereo-plotting machines to make use of the photographs, the use of electromagnetic distance-measuring equipment (by this means precise traverses were measured from Dover to Cape Wrath and from Land's End to East Anglia), the trials of an automatic stereocomparator using punched cards, the installation of automatic reading planimeters for measuring areas on the 1:2,500 plans, and new economical methods of multi-coloured printing.

One of the most interesting achievements has involved the completion of a new geodetic connexion across the English Channel, in conjunction with the Institut Géographique Nationale. Both angular and electromagnetic distance measurements were made from points near the coast of the Isle of Wight, Portland Bill and the Cotentin peninsula, with the collaboration of the Royal Corps of Signals and a Hydrographic Survey Ship in mid-Channel. Similar enterprises in recent years have linked the geodetic systems of Scotland and Scandinavia, using radar and a high-flying aircraft, and have tied Rockall into the triangulation network.

The Ordnance Survey's annual report for 1963-64\*, with a few pages of text, numerous statistical tables, and some 'progress maps', summarizes in prosaic form a wealth of fascinating cartographical activity. A gross expenditure of almost £5 million was partially offset by receipts of nearly £1½ million; the balance has indeed been spent to good account. In the words of the Director General, this work is "... not only of the highest importance but also of abundant and abiding interest to those who do it".

F. J. MONKHOUSE

## EARTH SCIENCES IN THE U.S.S.R.

THE following account is based on articles in the journal *Priroda*. A general review of the whole field of present-day research is provided by D. I. Shcherbakov (the editor of *Priroda*) and A. L. Yanshin (1, 44; 1963), who discuss geochronology, biostratigraphy, palaeomagnetism, tectonics, tectonic maps, spores and algae of Precambrian age, ore deposits and methods of survey and prospecting. The last subjects are also discussed by M. F. Grin (7, 2; 1954), who describes exploration in search of petroleum, natural gas, coal, phosphorites and iron ores.

Geological cycles and tectonics are discussed by N. F. Balukhovskiy (2, 54; 1963), E. D. Sulidi-Kondratiev and V. V. Kozlov (1, 102; 1964), G. P. Tamrasyan (1, 107; 1964) and D. A. Frank-Kamentsky (1, 110; 1964). A. I. Rybin (7, 87; 1964) discusses the causes of the deep-seated gravitational tectogenesis and outlines a hypothesis which would link-up deep-seated movements of the Earth's crust with the Earth's contraction and the phenomenon of isostasy.

Geochemistry, a branch of science highly cultivated in the Union, is represented by the articles of A. A. Drobkov (8, 45; 1963), who discusses chemical elements present in the living matter; V. V. Kovalsky (3, 44; 1964) discusses geochemical ecology in living matter, while A. I. Perel'man (5, 8; 1964) proposes a geochemical classification of chemical elements based on their abundance, distribution and migration capacity in the outer geospheres, introducing a new term "coefficient of hydrous migration". Finally, L. S. Tarasov (8, 3; 1963) most ably presents the hypothesis of the formation of geospheres as proposed by A. P. Vinogradov and his collaborators. According to this hypothesis the original Earth in its composition was similar to the composition of chondrite meteorites, and in the course of time, under the action of localized radiogenic heat, a process analogous to that of 'zone melting' in metals separated the volatile-enriched portions from the refractory components. Laboratory experiments of zone melting of a chondritic meteorite showed the

'frontal' zone enriched in silica and the 'rear' zone enriched in olivine. Applying this process to the primitive Earth one would postulate a degasification of the original material and formation of the atmosphere, hydrosphere and lithosphere through geochemical migration of elements.

Methods of study are discussed by V. N. Florovskaya and L. I. Ovchinnikova (11, 69; 1963), who describe the study of coals, bitumens and fossil plants by means of the 'luminescent microscope', using ultra-violet light. Ya. L. Blikh and V. M. Bondarenko (9, 85; 1964) describe

a 'deep-seated' geological survey method, measuring the intensity of cosmic rays in boreholes and mines.

Among accounts of new discoveries is the article by V. P. Solonenko (9, 102; 1964), who describes a newly discovered volcanic region in Eastern Siberia, in which 15 volcanoes of Quaternary age have been mapped and numerous traces of earthquakes recorded. This region is centred on the Udokan ridge situated between the rivers Vitim and Olekma, both tributaries of the River Lena. Siberian mosses of the Permian era, first discovered by M. F. Neiburg in 1941, are described by S. V. Meien (5, 73; 1963).

## TWENTY-FIVE YEARS OF CRUDE OIL PRODUCTION IN GREAT BRITAIN

IN 1939 production of crude petroleum from English oilfields amounted to 3,145 tons; in 1963 the total was 122,764 tons. After a quarter of a century it is interesting to take stock of the enterprise and expertise which have made possible this progress, humble though it may seem when measured by overseas standards. This has recently been done by R. G. W. Brunstrom of the Exploration Department, British Petroleum Co., Ltd., London, in an article entitled "BP's First Quarter Century of Crude Oil Production in Britain" (*BP Magazine*, No. 13, 1964; London). Actually, the first oilfield discovered in Britain was at Hardstoft, Derbyshire, in 1919, drilled for the then Ministry of Munitions, which ceased further explorations for oil in 1922. For various reasons private companies did not pursue the quest until some years later; it was, in fact, the Petroleum (Production) Act, 1934, which created the fillip to industrial enterprise in oil finding. This act vested in the Crown the ownership of all mineral oil not discovered to that date; it supplied just the attractive operating conditions under which oil companies felt justified in spending energy, time and particularly large sums of money in the search for oil in Britain. British Petroleum pioneered this new phase by drilling wells in the southern counties between 1936 and 1938, for example at Portsdown, near Portsmouth, and in Dorset, but with no success. But in the latter year natural gas was struck at Cousland, Midlothian; early in 1939 it was found at Eskdale, Yorkshire. A freak find was that of a shallow field at Formby, near Southport, Lancashire, in May 1939, which has produced more than 9,800 tons of crude oil since then, but with no geological encouragement of commercial extension. Soon after Formby came the well-known discovery of oil at Eakring, Nottinghamshire, a significant turning point in this history. "Eakring, apart from being a significant oilfield in its own right, was

immediately seen to be the first of a group of similar fields awaiting discovery. Formby brought hope of further success, but Eakring brought certainty." Eakring owed much to geological acumen at the time; coal mine and borehole evidence, confirmed by seismic refraction surveys, helped to establish it and, by continuation particularly of the geophysical technique, other discoveries in that region were made—Kelham Hills, 1941, Dukes Wood, 1941, Caunton, 1943. A small field discovered at Nocton, south of Lincoln, in 1943 yielded 40 tons of oil, then went to water. Although numerous exploration wells were drilled during the ensuing 10 years, they were not successful until a field was discovered at Plungar, Leicestershire, in 1953. A technique known as 'secondary recovery', that is, injection of water through wells drilled around the periphery of an oilfield, driving oil towards the production wells by a water flood, had been successfully employed to arrest decline in production in the Eakring group, and by 1953 had become standard practice in most British fields. The discovery of Egmont oilfield in 1955 started another bout of exploration activity which has continued to the present time. "An average of one new oilfield has been found in the East Midlands in each of the last seven years, and three new gas fields have been found but are not yet in production. The new fields are of varying sizes, and the largest, Gainsborough, is probably as big as Egmont." One particularly gratifying success is recorded from Kimmeridge, Dorset, where a 943-ft. well was drilled in 1937 and abandoned as a dry hole; a well drilled to 1,791 ft. near the same site in 1959 found oil and thus the Kimmeridge oilfield came into being. It is noteworthy that: "Up to the present there have been only three non-BP oil wells in Britain—one at Hardstoft and two at the small Esso field named Midlothian, near Dalkeith, Scotland".

## ARID ZONE FORESTRY

THE subject of afforestation and reforestation in arid zones is dealt with comprehensively in a publication entitled *Tree Planting Practices for Arid Zones\**, which has recently been revised by Dr. A. Y. Goor for the Food and Agriculture Organization of the United Nations.

About one-third of the world's land surface lies in the arid and semi-arid zones where the annual rainfall is less than 24 in. The arid zone, with less than 12 in. of rainfall a year, includes some of the great deserts of the world, but it is in parts of the semi-arid zone that afforestation and reforestation schemes have been and are being tried. These schemes and others aimed at improving the natural tree growth can make a useful contribution to the general

welfare of the peoples by bringing to localized areas a lessening of wind erosion, a reduction of evaporation from the soil and of plant transpiration, and in fixing moving sand, arresting gully and sheet erosion, in providing aesthetic benefits and in supplying timber and other products. But where the forester is called on to try to bring about these improvements through trees, he is usually faced with a set of climatic and edaphic factors which does not make his task an easy one. Very often he has to deal with soils that have been degraded by over-grazing, fire or over-cutting. He is often very restricted in the choice of species for planting and has to rely on a limited number of drought-resistant ones. The forester working in these conditions will find this handbook very useful, for it includes methods of seed collection and its handling, nursery and planting techniques. Perhaps some

\* Food and Agriculture Organization of the United Nations. FAO Forestry Development Paper No. 16: *Tree Planting Practices for Arid Zones*. Pp. xii+233+2 maps. (Rome: Food and Agriculture Organization of the United Nations; London: H.M.S.O., 1963.) 15s.; 3 dollars.

reference might have been made to the use of *Opuntia* or some other live hedging for nurseries.

The last two chapters on plantations are interesting, and irrigation is dealt with in some detail. Afforestation in such conditions is usually thought of as being uneconomical and written off as necessary protective measures on difficult sites. However, there is a body of opinion which considers that trees have sometimes been planted for protection of a watershed when, in the particular circumstances, a well-managed pasture would have provided just as much protection and possibly, in an arid zone, allowed more water to filter down to the valleys below. Indeed, it has now been demonstrated in some arid regions that forest trees established on better soils than has been

usual to allocate to this type of work in the past are providing favourable returns on the investment. In fact, forestry has proved itself to be the most economic of the various land uses possible. But why should these plantations be given the special name of "forest tree orchards"?

There are two appendixes on tree species used in arid zone afforestation and on seed collection, extraction, storage and pre-treatment practices, also listed by species. The two maps show the distribution of arid homoclimates for the eastern and western hemispheres. The list of selected references is adequate, but the more recent *Exotic Forest Trees of the British Commonwealth* (Streets, Oxford University Press, 1962) should have replaced Troup's publication with a similar title. C. J. TAYLOR

## NEW FOSSIL APES FROM EGYPT AND THE INITIAL DIFFERENTIATION OF HOMINOIDEA

By PROF. E. L. SIMONS

Department of Geology, and Peabody Museum, Yale University, New Haven, Conn.

THE third Yale Paleontological expedition to Egypt (November 1963–March 1964) supported by a U.S. National Science Foundation grant in geology (P-433) concentrated fossil-collecting efforts on a locality (I) in the upper levels of the Qatrani Formation, Oligocene of Egypt, which had yielded a few surface finds of early Anthropoidea in the previous season (January 1963). Extensive excavation at this quarry last winter, primarily during December and January, produced a considerable series of continental vertebrates, particularly rich in primates. Eleven mandibles and more than thirty isolated teeth of primitive Anthropoidea were recovered in addition to two jaws found in the previous season.

These finds add considerably to our understanding of the origins of Old World Higher Primates including, potentially, the ancestors of man at that period. Among these new primate materials are several interesting juvenile specimens of *Apidium phiomense* Osborn<sup>1</sup>; another represents a new large species of *Parapithecus*. The primary purpose of this article, however, is to describe briefly two wholly new and somewhat unexpected genera and species of Primates which were recovered in the collections from Quarry I. These and some 90–100 other Fayum primate specimens from lower horizons are to be illustrated and discussed by me in a forthcoming monograph on early Cainozoic mammalian microfaunas of the Fayum. However, in view of widespread interest in higher primate origins it seems advisable to record taxonomically at the present time the two most significant new species.

### Geological Horizon

The locality which yielded the new primates described here is appreciably higher stratigraphically than the classic fossil-vertebrate localities of the Fayum region, and is approximately that of the "upper level" of Osborn<sup>1,2</sup>. From this upper fossil wood zone came specimens which Osborn described as the types of a rodent *Metaphiomys beadnelli*, a primate *Apidium phiomense*, and a creodont carnivore *Metasinopa fraasi*. Evolutionary advances in the fauna at Quarry I, compared to those of the lower levels, suggest that considerable time elapsed between accumulation of these faunas, but at present it is not possible to say more than that most species appear to be different from those of the lower zones. For example, examination of Fayum rodents by A. E. Wood, soon to be published, have shown that a common rodent of this upper level, *Metaphiomys beadnelli*, is not present at the next lowermost Quarry (G) in the section, but that a

smaller, more primitive species of *Metaphiomys* that could be ancestral to *M. beadnelli* occurs in Quarry G. Similarly at Quarry G a small species of *Apidium*, *A. moustafai*, is abundant. *A. moustafai* is almost certainly ancestral to the much larger *A. phiomense* of the Quarry I level. Apparently the type specimen of the archaic hominoid primate *Propithecus haeckeli* Schlosser<sup>3</sup> came from about the level of Quarry G, or even lower in the section. For a left  $M_1$ , indistinguishable from that of *P. haeckeli*, has been recovered from Quarry G. Other teeth of *Propithecus* sp. from Quarry G are appreciably larger and somewhat different in morphology from those of the type species, *P. haeckeli*. At the Quarry I level no teeth of *Propithecus haeckeli* have been found, but instead only those of a generally larger and more advanced primate species. Taken together these evolutionary differences between the faunas of the two upper quarries, G and I, their stratigraphical separation by more than 250 ft. of varying, partly cyclothemmic sediments, including riverine sands, marine limestones and marls, indicate that the fauna of Quarry I represents the latest known Oligocene fauna of Africa and one which is distinctly different from the classic Fayum faunas examined by Andrews<sup>4</sup> and Schlosser<sup>3</sup>.

### Systematics

Order, PRIMATES

Superfamily, HOMINOIDEA

Family, Pongidae

Genus *Aegyptopithecus*<sup>5</sup>, gen. nov.

Type: *Aegyptopithecus zeuxis*<sup>5</sup>, new species.

**Generic characters:** Lower dental formula 2.1.2.3, size approximately that of a gibbon and 25 per cent larger than the type of *Propithecus* in most comparable measurements. Differs from its contemporary *Propithecus* in showing relatively larger canine, premolar heteromorphy and relatively larger  $M_2$  and  $M_3$ . Resembles *Proconsul* in marked molar size increase posteriorly.  $M_1 < M_2 < M_3$ , but differs from members of the latter genus, *Pliopithecus* and *Dryopithecus*, in possessing a more triangular  $M_3$ , narrowing posteriorly; unlike most *Proconsul*, entoconid and hypoconulid (rather than hypoconid and hypoconulid) joined by distinct crest. Resembles *Dryopithecus* in rounded outline of  $M_{1-2}$  but unlike later dryopithecines retains lower and more rounded molar cusps, as in *Propithecus*. Ascending ramus of mandible approximately 40 per cent broader from front to back compared with depth of horizontal

ramus at  $M_2$  than in *Propithecus*; ascending ramus of mandible more vertical relative to the tooth row than in *Propithecus* or *Proconsul*, probably indicating comparatively short face.

While resembling *Propithecus*, *Aegyptopithecus* is clearly much closer to Mio-Pliocene dryopithecines particular to East African Miocene species of this group which it agrees with in showing unusually marked molar size increase posteriorly. At the symphysis, however, *Aegyptopithecus* is more typically pongid than some members of the East African species of *Proconsul*, and shows comparatively less anteroposterior thickening of the symphysis and a more backward-directed simian shelf. The characters of symphyseal robusticity and degree of development of simian shelf are notably variable in living hominoids<sup>6</sup>. In *Proconsul nyanzae* and *Proconsul major* this shelf is usually more ventrally directed than in *Aegyptopithecus*.

*Aegyptopithecus* is close in size to *Pliopithecus* (*Limnopithecus*) from East Africa but differs from it and from European *Pliopithecus* in showing more distinct labial cingula, relatively smaller premolar and molar trigonids, less distinct cross-crests between protoconid-metaconid and entoconid-hypoconid, relatively much larger  $M_3$  with narrower  $M_3$  talonid, and comparatively larger  $M_3$  hypoconulid. Being much earlier and more generalized than *Dryopithecus* or *Proconsul*, *Aegyptopithecus* does show some likeness to *Pliopithecus* (*Limnopithecus*), which Ferembach<sup>7</sup> has maintained may have greater affinity with the great apes (pongines) than with the gibbons. However, resemblance between all the East African and Egyptian hominoids of the Oligocene and Miocene is great. In general, they exhibit the sort of morphological interrelationship to be expected of various members of a category comparatively close to the time of its initial radiation. These interrelationships which are reasonably apparent in early hominoids naturally affect all attempts to place given species in higher categories. Dental features now seen only in gibbons or only in the African apes (*Pan*, *Proconsul*) were then combined in one species as Ferembach's observations show.

Since it is characteristic of African *Pliopithecus* (*Limnopithecus*), European *Pliopithecus* and modern gibbons to have lower third molars which are shorter or equal in size to  $M_2$  (and other features cited here), this new Fayum primate would appear to relate more definitely to the ancestry of *Proconsul*. The comparatively enlarged  $M_3$  of *Aegyptopithecus* and of *Proconsul* species is one of the few features which seem to differentiate species of the latter from the type species of *Dryopithecus*, *D. fontani*. Moreover, if some Fayum primates are near the ancestry of later Hominoidea, as certainly appears to be probable, another contemporary of *Aegyptopithecus* (described here) would seem to be a much better candidate for possible ancestry to the gibbons of Miocene-Recent times.

*Aegyptopithecus zeuxis*<sup>8</sup>, new species

Type: C.G.M. 26901, left mandibular ramus with  $P_4$ - $M_2$ ; partial alveoli of  $C$ ,  $P_3$  and  $M_3$  and symphysis.

*Hypodigm*: Type and Yale Peabody Museum (Y.P.M.) 21032, left horizontal and vertical ramus with broken  $P_4$ ,  $M_1$ - $M_3$ , American Museum of Natural History (A.M.N.H.) 13389, left mandibular ramus with broken  $C$ ,  $P_3$  roots and alveoli of  $P_4$ - $M_3$ .

*Horizon and Locality*: Yale Expedition Quarry I, upper fossil wood zone, Qatrani (Fluviomarine) Formation, Oligocene, Fayum Province, Egypt, U.A.R.

*Specific characters*: Not distinguished from generic.

The three known mandibular rami complement each other in parts preserved although the reference of A.M.N.H. 13389 to this species remains slightly in doubt in view of its fragmentary condition and uncertain locality and horizon; it was collected in 1906.

Family, (?) Hylobatidae

Genus *Aeolopithecus*<sup>8</sup> gen. nov.

Type: *Aeolopithecus chirobates*, new species.

*Generic characters*: Lower dental formula 2.1.2.3. Slightly smaller than *Propithecus* and much smaller than all other Oligocene-Recent hominoids. Differs from the contemporary genus *Propithecus* in showing marked premolar heteromorphy (sectorial  $P_3$ ), comparatively much larger canines and more procumbent incisors and from both *Aegyptopithecus* and *Propithecus* in having tooth rows more divergent posteriorly and in showing relatively higher and deeper genial fossa, with horizontal ramus of mandible shallowing posteriorly. Differs from *Pliopithecus* in possessing relatively larger canines, and greater degree of premolar heteromorphy. Resembles some *Hylobates* and differs from *Aegyptopithecus*, European *Pliopithecus* and *P. (Limnopithecus)* in having much reduced  $M_3$ .

Fig. 1. Crown view of the left mandibular teeth of the type of *Aegyptopithecus zeuxis*, C.G.M. 26901, with  $M_3$  restored from Y.P.M. 21032. ( $\times 4.00$ )

Fig. 2. Lateral view of the left lower jaw of *Aegyptopithecus zeuxis* Y.P.M. 21032 with  $P_4$  restored from C.G.M. 26901. ( $\times c. 1.50$ )

Although molar crown patterns are obscured by destruction of the enamel the observable characters of the mandible and teeth all suggest that this primate is related to the gibbons, living and fossil. Particularly pertinent to this conclusion are the large and long canines, reduced  $M_3$  and posterior shallowing of the mandibular ramus. As in some *Hylobates* the genial fossa is remarkably high and deep.

In size *Aeolopithecus chirobates* is rather larger than *Oligopithecus savagei* and *Parapithecus fraasi*. It also comes from a higher horizon than either of the latter species. *A. chirobates* differs from *Oligopithecus savagei* not only in size and proportion of the mandibles (the mandible shallows less posteriorly in the latter), but also in that the mental foramen is located much farther forward, the canines are relatively larger and the premolars more heteromorphic. Molar crowns of *Aeolopithecus chirobates* also appear to lack the cross-crests of *Oligopithecus savagei*. Close relationship of *Aeolopithecus chirobates* to *Apidium phiomense*, *Apidium moustafai* or *Parapithecus fraasi* is ruled out by their differing dental formulae and wholly dissimilar tooth morphologies.

This is one of the most distinctive of Fayum primates known so far and it is regrettable that only one specimen exists. However, it is the second most complete specimen of an Oligocene primate mandible known, after the type of *Parapithecus fraasi* (S.M.N. 12639a), and it should provide data for useful comparative analysis when early gibbons become better known.

The most direct relationships of this species are with *Pliopithecus*, particularly sub-genus *Limnopithecus* which possesses a similarly large simian shelf and with which *Aeolopithecus* agrees in most other observable features except for its much smaller size. Conceivably *Aeolopithecus* is closer to the line that gave rise to modern *Hylobates* and *Symphalangus*, that is, *Pliopithecus*, in view of its third molar reduction, as is also observed in some species of *Hylobates*. Nevertheless, adoption of such a conclusion on the strength of this one feature alone seems inadvisable. It remains entirely possible that none of the known fossil gibbons is actually ancestral to present-day south-east Asian species.

In the early part of this century Fourtau<sup>10</sup> described a species, *Prohylobates tandyi*, from the supposed Burdigalian (early Miocene) fauna of Wadi Moghara, west of Alexandria, Egypt. As the name implies, he concluded that this fossil was related to the gibbons. Consequently, it is necessary to consider the relation of this primate to *Aeolopithecus*. Examination shows clearly that *Prohylobates tandyi* is a cercopithecoid monkey, a fact missed

by most previous commentators on its status (including Remane<sup>11</sup>, MacInnes<sup>12</sup>), although Le Gros Clark and Leakey<sup>13</sup> did remark "the molars [of *P. tandyi*] appear to be more cercopithecoid in their cusp pattern". This is a typical example of the danger of publishing discussion on fossils which have not actually been seen and compared with other pertinent materials. *Prohylobates tandyi* is clearly congeneric and probably conspecific with a still undescribed cercopithecoid monkey which occurs in the Miocene Rusinga Island fauna of East Africa, and consequently bears no taxonomically significant relationship to *Aeolopithecus*.

#### *Aeolopithecus chirobates*<sup>18</sup> new species

**Type:** C.G.M. 26923, complete horizontal rami of mandible fused at symphysis with incisor alveoli and left and right  $\bar{C}-M_3$ .

### General Discussion

In determining the position of given fossils in evolutionary trees it is often necessary to make use of inferences which cannot be tested in full but which often serve as a basis for further investigations. One of these is that many Egyptian Oligocene primates are likely to be in or near the ancestry of later monkeys, apes and men. Students of fossil mammals know that there is little evidence of the occurrence of higher primates (Anthropoidea) in the known Eocene, Oligocene and early Miocene faunas of Eurasia; thus pointing to the continent of Africa (where Oligocene and Miocene Primates are abundant) as the most probable place of differentiation of monkeys, apes and men. Of course, were early and middle Cenozoic faunas better known in Asia, distribution of early Anthropoidea might be extended. Recent review of the early Cainozoic primates of Europe<sup>16,17</sup> has shown that none of the known Eocene primate species of that continent is a good candidate for possible relationship to the ancestry of monkeys, apes or men. One species, *Alsaticopithecus lemani*, described by Hürzeler<sup>18</sup> from middle Eocene deposits in Alsace, has been tentatively suggested as having molar resemblance to Anthropoidea by several authors, as indeed it does. However, McKenna<sup>19</sup> has correctly identified this species as a member of the family Microsyopidae. It thus belongs to a doubtfully primate family known otherwise only from the Eocene of North America. Microsyopid molars parallelistically resemble those of certain hominoids, but it is unlikely that Old World higher primates are derived from Microsyopidae or anything like them.

The only remaining, possibly hominoid, primates of early age outside Africa are from the late Eocene of

Burma: *Pondaungia cotteri*<sup>20</sup> and *Amphipithecus mogaungensis*<sup>21</sup>. The original materials of both these species have been examined during the process of preparing this article, but the fragmentary condition of the types of these two forms precludes a definite statement that the origins and early geographic distribution of Old World higher primates were extended or were centred outside Africa.

The type of *Pondaungia cotteri*, which was quite inadequately figured and described by Pilgrim, consists of partial mandibular rami of both sides of the lower jaw carrying chemically corroded second and third molars. As nearly as can be judged, in size, outline and cusp placement, these molars resemble those of *Propliopithecus*. Associated with the two mandibular fragments of *Pondaungia* at the site of discovery was a left maxillary fragment with  $M1-2$ , apparently belonging to the same individual.

Pilgrim's figures<sup>20</sup> and discussion of *Pondaungia* left much to be desired and indeed, on the basis of the data he then provided, it was scarcely possible to make an ordinal placement for the form. Consequently, most publications on early Old World primates since 1927 either omit *Pondaungia cotteri* or question placement of this species as a primate.

Pilgrim noted that web-like chemical erosion of the enamel of lower right and left  $M2-3$  obscured their crown patterns. He also supposed this to be the case for the upper molar surfaces. However, microscopic examination of the type at Calcutta indicates that, while the lower molars do appear to have suffered erosive damage, the grooves and ridges on the upper teeth represent natural surfaces except in one or two broken areas. Thus it is

possible to observe upper molar structure in considerable detail in *Pondaungia*. These molars have the typical placement of the four primary cusps, pronounced lingual cingula and crenulate occlusal surface characteristic of most early hominoids, but multiple cusps exist in the region of paraconule and metaconule and there are no ridges connecting any of the main cusps.

In the combination of these molar features, *Pondaungia* somewhat resembles species of the European Eocene tarsioiid genus *Microchoerus* and members of the North American omomyid primate genera *Hemiacodon* and *Ourayia*. It is tempting to interpret molar crown structure in *Pondaungia* as morphologically transitional between that characteristic of Omomyidae and that of Pongidae, but there are non-Primates which *Pondaungia* also resembles, particularly some species belonging to the hypsodontid Condylarthra. This archaic mammalian family is not definitely known to have occurred in Asia, but its presence there in the late Eocene would not be particularly surprising. The evidence on the taxonomic relationship of *Pondaungia* is therefore equivocal but, rather than regarding it as *incertae sedis*, the balance would seem to weigh in favour of a questioned placement among *Hominoidea*—archaic members of which it resembles in known comparable parts.

From the Pondaung Formation of Burma is the type of *Amphipithecus mogauensis* Colbert<sup>21</sup> (Fig. 4). Colbert's reasons for placing this animal among the higher primates remain acceptable and have been strengthened by its dental resemblance to the recently discovered Fayum primates *Oligopithecus savagei* and *Aegyptopithecus zeuxis*. In its mandibular depth, foreshortening of the anterior dentition, and symphyseal cross-section this species is typically hominoid. Indeed, Colbert made a queried reference of the species to the taxonomic family of the apes—Simiidae, now Pongidae. Unfortunately, only two premolars and first molar of the left side are preserved in the type and only specimen. Roots of a canine and a  $P_3$  are also evident and if his identification of these teeth is correct this means that three premolars were present. Although all later Old World Anthropoidea, with the exception of the Parapithecidae, possess only two premolars above and below, the occurrence of three here is presumably a primitive feature. Most other Eocene Primates had at least three premolars. Taken altogether, the structure of the teeth and jaw fragment of *A. mogauensis* permits its close taxonomic association with the early apes of the Fayum, but it is regrettable that so little is known of this species. Since this is the case, understanding of its full significance must wait until more material is secured. It is clear, as Colbert quite adequately demonstrated, that this fragment is more like comparable parts of early catarrhines than like members of any other known order of Mammalia. The conclusion which must be drawn is that known materials of *Pondaungia* and *Amphipithecus* indicate, but do not prove, that early hominoids or hominoid-like primates existed in the Asian tropics before the end of the Eocene Epoch. The question whether these species bear any relation to the latter radiation of apes, man and monkeys of the Old World cannot really be settled on the basis of evidence available at present.

Consequently, the Fayum primates of Egypt remain the only adequate basis for speculation as to the nature of the early stages of differentiation of the higher primates of the Eastern Hemisphere. The following tentative conclusions as to their phylogenetic meaning are consequently presented.

*Propithecus haeckeli* Schlosser<sup>3</sup> has most often been treated as representing an ancestral gibbon or at least a good morphological antecedent for Mio-Pliocene *Pliopithecus* species. Although Schlosser<sup>3</sup> in his original description stressed this point of view, his comparisons between *Propithecus* and *Pliopithecus* are not very specific and he equally considered a number of other

phyletic relationships for *Propithecus*, including the possibility that it was ancestral to *Pithecanthropus* and modern man. Of course, at the time of his writing there were not many other fossil Higher Primates for comparison. Afterwards, with more comparative material available, Gregory<sup>22</sup>, Abel<sup>23</sup> and Le Gros Clark<sup>24</sup> also stressed resemblances between *Propithecus* and European or East African *Pliopithecus*. More recently, in the most comprehensive investigation of *Pliopithecus* published so far, Hürzeler<sup>25</sup> questioned that *Propithecus haeckeli* could be ancestral to the Mio-Pliocene gibbons. He noted that in this Egyptian species there is no  $P_3$  sectoriality, that the anterior fovea of  $P_4$  does not open on the lingual side as in *Pliopithecus* species and the metaconid crest of  $P_4$  of *Pliopithecus* is lacking in the Fayum primate, which instead possesses a labial cingulum not seen in *Pliopithecus*. Moreover, in *Propithecus* a weak crest exists between  $M_3$  hypoconid and hypoconulid while in *Pliopithecus* instead a crest joins entoconid and hypoconulid. In *Propithecus* the lower molar cusps are lower and more rounded and lack much of the crown-crenulation and development of accessory tubercles common in *Pliopithecus*. All these distinctions, when taken together with the now documented presence of a rather more *Pliopithecus*-like species, *Aeolopithecus chirobates*, contemporary with at least one species of *Propithecus* in the Fayum, suggest that *Propithecus haeckeli* should not be thought of as taxonomically close to the gibbons.

In its overall morphology, the type mandible and dentition of *Propithecus haeckeli* (S.M.N. 12638) is more reminiscent of what one would expect to see in an Oligocene forerunner of the family Hominidae rather than in an early dryopithecine or gibbon. The probability that this primate indicates that, by early Oligocene times, species ancestral to living man had already differentiated from those which led to *Dryopithecus* and subsequent great apes is thus increased. Confirmation of this interesting possibility will not come unless Oligocene-Miocene forms transitional between *P. haeckeli* and *Ramapithecus punjabicus* of the late Miocene of Africa and Eurasia are recovered by future field research in relevant areas of the Old World.

## ACTIVATION OF LYSOSOMES BY OXYGEN

## Oxygen-induced Resorption of Cartilage in Organ Culture

FOLLOWING the *in vivo* observations of Johnson on the distribution of tissue types in bone tumours and the correlation between this distribution and the blood supply<sup>1</sup>, it has been demonstrated that exposure of skeletal tissues in culture to elevated partial pressures of oxygen causes resorption and may affect the differentiation of the tissue<sup>2,3</sup>. The mechanism of this effect has not been explained.

In the experiments recorded here, the effect of high partial pressures of oxygen on the cartilaginous limb-bone rudiments from embryonic chicks has been investigated in organ culture. The histological changes produced in the explants closely resemble those caused by exposure to excess vitamin A (ref. 4), and the possibility that both agents act through the same mechanism, increased release of proteolytic lysosomal enzymes<sup>5</sup>, has therefore been explored.

Tibiae and femora from eight-day chick embryos were cultivated on stainless-steel grids<sup>6</sup> in a chemically defined medium based on that described by Biggers *et al.*<sup>7</sup> and containing 0.5 per cent bovine serum albumin. In certain experiments cortisol hemisuccinate was added at either 1.0  $\mu\text{g}/\text{ml}$ . or 0.1  $\mu\text{g}/\text{ml}$ . One of each pair of rudiments received experimental treatment and the other was grown under control conditions. The cultures were incubated at 37.5° centigrade in air-tight glass chambers<sup>8</sup> in which the gas phase was either 85 per cent oxygen with 5 per cent  $\text{CO}_2$  or 20 per cent oxygen with 5 per cent  $\text{CO}_2$ . The medium was collected and the cultures re-fed and gassed at two-day intervals. At the termination of the experiment, usually after six days, representative rudiments and their controls were fixed for histological examination and the remainder were assayed for enzyme content.

The medium was cooled in ice and adjusted to pH 5.0 with hydrochloric acid. Acid phosphatase was estimated with sodium nitrophenol phosphate as substrate<sup>9</sup> and acid protease with haemoglobin as substrate<sup>10</sup>. The cartilaginous rudiments were homogenized in 0.25 M sucrose and a particulate preparation sedimented at 200,000g/min. The enzyme activity of this pellet (the bound activity) was determined after re-suspension in a neutral detergent, and the activity of the supernatant (the free activity) was also estimated. Since both acid phosphatase and acid protease are of lysosomal origin, the ratio of their free to total activities was taken as a measure of the stability of the lysosomes to the stress of homogenization.

The effect of high oxygen was quite striking. The longitudinal growth of the rudiments was greatly reduced and they became abnormally translucent and soft. Histological sections showed a severe loss of metachromatic material throughout the rudiment and especially marked in the hypertrophic zone (Fig. 1). The periosteal layer of osteoblasts was much thicker in the oxygen-treated explants. Accompanying these histological changes were a greatly increased production and release of acid phosphatase and protease, and the percentage of free enzyme was elevated in the oxygen-treated rudiments (Table 1).

Table 1. OXYGEN-INDUCED RELEASE OF ACID PROTEASE  
Figures are percentages of the control values in that experiment

	Released into medium	Total synthesized	Free/total
Air	100	100	100
85% $\text{O}_2$	130	136	186
85% $\text{O}_2$	100	100	100
85% $\text{O}_2$ with cortisol (1.0 $\mu\text{g}/\text{ml}$ .)	55	73	78

Fig. 1. Top, 8-day tibia cultured 6 days with gas phase of 85 per cent oxygen; bottom, paired rudiment in air. (Toluidine blue,  $\times c. 7.3$ )

Fig. 2. Top, gas phase 85 per cent oxygen; bottom, paired tibia with gas phase 85 per cent oxygen; 0.1  $\mu\text{g}/\text{ml}$ . cortisol. (Toluidine blue,  $\times c. 7.3$ )

Since cortisol largely inhibits lysosomal instability produced by a number of agents<sup>11,12</sup>, it was tested in this system. At both 1.0  $\mu\text{g}/\text{ml}$ . and 0.1  $\mu\text{g}/\text{ml}$ . this steroid prevented the excessive release of enzyme (Table 1) and the loss of metachromatic ground-substance (Fig. 2). The increased stability of the lysosomes was reflected in the reduced percentage of free enzyme (Table 1).

To correlate the loss of ground-substance specifically with the release of acid protease, cultures were grown in the presence of the protease inhibitor, epsilon-amino-n-caproic acid<sup>13</sup>. This agent, at 0.1 M concentration, has been found to be non-toxic and to inhibit the vitamin A-induced loss of ground-substance in the limb-bone rudiments of embryonic chicks<sup>14</sup>. The oxygen-induced loss of ground-substance was also largely prevented by this protease inhibitor (Fig. 3).

These results suggest that, in this system, high partial pressures of oxygen act like vitamin A, that is, by alteration of the lipoprotein lysosomal membrane, allowing escape of hydrolytic enzymes and consequent degradation of the ground-substance<sup>15</sup>. This view is supported by the inhibitory effect of cortisol and of epsilon-amino caproic acid.

Fig. 3. Top, gas phase 85 per cent oxygen; bottom, paired tibia with gas phase 85 per cent oxygen; 0.1 M  $\epsilon$ -amino caproic acid. (Toluidine blue,  $\times c. 7.3$ )

To ascertain whether oxygen acts directly or indirectly, lysosome-rich suspensions were prepared from rat liver and kidney and incubated with 100 per cent oxygen, 100 per cent nitrogen, and air. There was no significant release of lysosomal enzymes under any of these three conditions. This confirms the results of de Duve<sup>16</sup> carried out with slices and crude lysosomal preparations from rat liver. The possibility remains that the lysosomes of skeletal tissues may respond differently to oxygen. Preliminary experiments indicate that lysosomal fractions prepared from embryonic chick cartilage are more susceptible to oxygen than are fractions prepared from liver and treated in the same manner. The question of whether oxygen *in vivo* acts directly on the lysosome or indirectly, perhaps through alteration of cell membrane permeability, remains unanswered. We had planned to pursue this point with histochemical investigations on monolayer cultures, when we became aware of the work of Allison, reported in the following article.

This phenomenon has important physiological implications. Cartilage is normally an avascular tissue. Invasion by blood vessels leads to its resorption and replacement by a tissue capable of existing in an oxygenated environment; this is the normal sequence of events in the epiphyseal plate. We suggest that a local rise in oxygen tension may cause an increased release of lysosomal enzymes from the cartilage cells. These enzymes include an acid protease which degrades the protein-polysaccharide complex of the ground-substance and facilitates invasion by vascular tissue.

We thank Dame Honor B. Fell for her advice.

## Role of Lysosomes in Oxygen Toxicity

THERE is substantial evidence that prolonged exposure to 95 per cent oxygen at atmospheric pressure or to hyperbaric oxygen produces toxic effects in animals<sup>1,2</sup> and cells in culture<sup>3,4</sup>. We have confirmed the toxicity of 95 per cent oxygen at atmospheric pressure using three systems of cultured cells and have made observations on the sequence of changes following exposure to hyperoxia.

HeLa cells and chick embryo cells were propagated and counted as previously described<sup>5,6</sup>, and counts of viable cells were made on the basis of resistance to staining with 0.01 per cent eosin in saline<sup>7</sup>. In the presence of air + 5 per cent CO<sub>2</sub>, logarithmic growth of HeLa cells continued for at least 6 days (Fig. 1). In the presence of 95 per cent oxygen + 5 per cent CO<sub>2</sub> limited growth was seen for 3–4 days, after which the number of viable cells decreased, paralleling observations of Rutter<sup>3</sup> on AH cells. The toxicity was evidently not due to deterioration of the medium, since medium taken from degenerating cells after growth under 95 per cent oxygen for 5 days supported normal growth of other cells under 20 per cent oxygen, and a change of medium had no beneficial effect on cells kept under 95 per cent oxygen.

Similarly, chick embryo cells in control cultures equilibrated with air + 5 per cent CO<sub>2</sub> remained in good condition for at least one week, whereas cultures exposed to 95 per cent oxygen + 5 per cent CO<sub>2</sub> showed toxic

Fig. 1. Counts of HeLa cells per culture when grown in the presence of air + 5 per cent CO<sub>2</sub> and 95 per cent oxygen + 5 per cent CO<sub>2</sub>.

Fig. 2. Chick embryo cells grown for 5 days in the presence of air + 5 per cent CO<sub>2</sub> (A) and 95 per cent oxygen + 5 per cent CO<sub>2</sub> (B) ( $\times c. 180$ ).

Fig. 3. Mouse macrophages cultivated for 3 days in the presence of air + 5 per cent  $\text{CO}_2$  (A) and 95 per cent oxygen + 5 per cent  $\text{CO}_2$  (B) ( $\times c. 160$ )

effects after the third or fourth day, including rounding, cytoplasmic granularity or vacuolation and nuclear changes (Fig. 2). Mouse macrophages were obtained by intraperitoneal inoculation of 3 ml. of culture medium (Parker's solution 199 (Glaxo) with 20 per cent calf serum heated at  $56^\circ$  for 20 min) containing 10 i.u. heparin per ml. into male mice of strain VSBS/NIMR weighing 18–20 g. After brief massage the cells were collected and dispensed in 1 ml. volumes in tubes containing small coverslips. Cultures equilibrated with air + 5 per cent  $\text{CO}_2$  remained in excellent condition for at least 2 weeks. Cultures equilibrated with 95 per cent oxygen + 5 per cent  $\text{CO}_2$  showed some rounding of cells by 36 h and progressively more severe changes thereafter (Fig. 3). A conspicuous change was 'ballooning' of the cells—which were round and much increased in size with some cytoplasmic vacuolation. Later the cells degenerated completely and many left the coverslips on which they had been grown.

To test whether lysosomal enzymes might be involved in these changes, cultures of unfixed macrophages were stained for acid phosphatase by the method of Gomori as described elsewhere<sup>8</sup>. Normal cells showed very little staining, whereas cells incubated in high oxygen showed phosphatase staining of lysosomes within 24 h (Fig. 4). As Bitensky<sup>9</sup> has pointed out in another context, this implies that the permeability of lysosomal membranes has been increased, because the  $\beta$ -glycerophosphate substrate does not penetrate into intact, healthy lysosomes. This stage—which we term first stage activation<sup>8</sup>—is reversible, and most macrophages exposed to 95 per cent oxygen for 24 h recover when cultured under 20 per cent oxygen. By 48 h of hyperoxia, second stage activation

Fig. 4. Mouse macrophages unfixed and stained for acid phosphatase by the Gomori technique. A, normal cells; B, cells exposed to 95 per cent oxygen + 5 per cent  $\text{CO}_2$  for 24 h. Note discrete staining of lysosomes, with some cells still fully extended. C, cells exposed to 95 per cent oxygen + 5 per cent  $\text{CO}_2$  for 48 h. All cells are rounded, and there is some diffuse cytoplasmic staining as well as intense lysosomal staining ( $\times c. 650$ )

is evident: enzyme is released from lysosomes into cytoplasm. This can be shown chemically (Fig. 5) as well as histochemically (Fig. 4). The lower total enzyme activity in cells exposed to hyperoxia may be explicable by release into the medium and, possibly, inactivation.

The question arises whether the increased permeability of lysosomal membranes in hyperoxia is a primary event or is secondary to some other change such as damage to the cell membrane. That cell membranes are sensitive to oxygen is shown by observations such as the lytic effect of hyperbaric oxygen on erythrocytes, especially those of tocopherol-deficient animals<sup>10</sup>. However, in the cells we have examined under high oxygen increased permeability of lysosomes is seen at least 12 h before the cell membranes become permeable to eosin; fluorescence microscopy reveals the penetration of even very small amounts of eosin into the cells. Moreover, the toxic effects of oxygen were markedly reduced by having in the culture medium 10–50  $\mu\text{g}/\text{ml}$ . chloroquine or hydrocortisone, both of which stabilize lysosomal membranes<sup>11,12</sup>.

Fig. 5. Enzyme activities in particulate and supernatant (hatched) fractions of macrophages cultured in air + 5 per cent  $\text{CO}_2$  or 95 per cent oxygen + 5 per cent  $\text{CO}_2$  ( $\text{O}_2$ ), homogenized and assayed under conditions similar to those described by Cohn and Wiener<sup>14</sup>. The particulate fraction was disrupted before assay, and results in oxygen-treated macrophages are expressed per mg protein, referred to 100 per cent as total activity per mg protein in controls. a, Acid phosphatase; b, acid DNase; c, acid RNase; d, acid protease

We suppose that hyperoxia increases the permeability of lipoprotein membranes of cells and cell organelles, probably as a consequence of lipid peroxidation. Tappel *et al.* have already demonstrated release of lysosomal enzymes from rabbit liver homogenates by lipid peroxidation damage<sup>13</sup>. Short exposures of liver slices or homogenates *in vitro* to oxygen were not found to release lysosomal enzymes<sup>14</sup>, but the results with cell cultures suggest that longer exposures may be necessary to produce demonstrable changes. In any event, it seems that the lysosomes of some cells are more susceptible to oxygen effects than those of other cells; the cartilage cells described by Sledge and Dingle in the preceding communication would be a case in point. Heppleston and Simnett<sup>4</sup> found that some cells were more susceptible to oxygen damage in organ cultures than other cells; for example, alveolar cells showed more severe changes than lung adenomata. The atrophy of germinal cells of the testis seen in animals exposed to chronic hyperoxia<sup>2</sup>, and in tocopherol deficiency, suggests that these cells are highly susceptible. The role of tocopherol as an antioxidant protecting lysosomes, which has already been raised by Tappel *et al.*<sup>13</sup>, deserves further investigation. It might be expected that tocopherol-deficient animals, and the lysosomes of cells isolated from them, would be very sensitive to hyperoxia. Moreover, the additive carcinogenic effect of hyperoxia and hydrocarbon carcinogens, which are selectively concentrated in lysosomes, directs attention to the role of these organelles in carcinogenesis<sup>15</sup>.

Although these results suggest that lysosomal enzymes play an important part in

oxygen toxicity, they do not exclude the possibility that other effects may exist, for example, oxidation of thiol groups of enzymes.

I thank Mr. C. Gilchrist for assistance and Mr. F. Wanless for the photomicrographs.

## DELINEATION OF THE THYMIC AND BURSAL LYMPHOID SYSTEMS IN THE CHICKEN

By DR. MAX D. COOPER\*, DR. RAYMOND D. A. PETERSON†  
and PROF. ROBERT A. GOOD‡

Pediatric Research Laboratories of the Variety Club Heart Hospital, University of Minnesota, Minneapolis

INVESTIGATIONS of clinical immunological deficiency syndromes have long suggested the existence in man of two distinct populations of lymphoid cells, a division seen most clearly in the Bruton type of sex-linked recessive agammaglobulinemia in which there is virtually complete failure of plasma cell formation<sup>1,2</sup> and  $\gamma$ -globulin production<sup>3</sup>. Many of these patients have never formed detectable antibody. Their immunological failure is only partial, however; they are able to express delayed hypersensitivity<sup>4,5</sup> and are usually able to reject homografts, although the rejection process is slower and less efficient than normal<sup>6</sup>. Circulating lymphocyte-levels are relatively normal in most instances. Thus, their immunological defect represents a relatively isolated absence of antibody-producing capability and of its cellular and humoral correlates, plasma cells and the immunoglobulins.

It has been possible, since the discovery of the immunological role of the mammalian thymus and the avian bursa of Fabricius, to produce immunological deficiency syndromes in experimental animals, provided the organs are removed in the early neonatal or post-hatching<sup>7-17</sup> period. However, none of the mammalian models of immunological defect, in the mouse, rabbit, rat, or hamster, has involved absence of immunoglobulins or lack of plasma cells<sup>13,15,18-20</sup>, although all involve some loss of antibody-producing capability. The only model approaching classical agammaglobulinemia has been that of the chicken bursectomized in the immediate post-hatching period or hormonally bursectomized by treatment with 19-nortestosterone or similar agents during incubation. Such birds produce low levels of antibody to most antigens<sup>7,8,21,22</sup> and are usually deficient in plasma cells and in  $\gamma$ -globulin, particularly the 7S component<sup>21,23-25</sup>. Data relating the thymus and bursa to reactions of delayed hypersensitivity are inconclusive<sup>21,26</sup>. Skin homograft immunity has been variably affected by neonatal thymectomy in different series of experiments<sup>21,27,28</sup>, but has been quite consistently uninfluenced by bursectomy.

Szenberg and Warner<sup>29</sup>, in 1962, on the basis of investigations of hormonally bursectomized chickens, some of which also had an atrophied thymic cortex, originally postulated a dissociation of immunological function based on thymic versus bursal influence. Since that time, additional evidence for this immunological dissociation has been forthcoming from several laboratories<sup>26,27,29-31</sup>. Further, the investigations of Peterson *et al.*<sup>32</sup> established

the role of the bursa in visceral lymphomatosis. This virus-induced malignancy seldom if ever occurs in bursectomized birds, while thymectomized chickens seem to be as susceptible as controls.

The chicken model, then, seemed to offer the greatest potential for separating the two cell systems experimentally, systems so clearly separated in that extraordinary 'experiment of Nature', sex-linked recessive agammaglobulinemia. The work to be described involved a combination of sub-lethal irradiation with bursectomy, thymectomy, or both in the immediate post-hatching period in chickens. It has enabled us to produce an experimental model of agammaglobulinemia, and to define the thymic and bursal systems in the chicken. The findings suggest that the thymus-dependent tissue is basic to immunological recognition, and that it interacts with the bursa-dependent lymphoid tissue which might be termed the production system for antibody. They suggest, too, that all the experiments in mammals demonstrating immunological deficiency following removal of the thymus or appendix, or both, have affected thymus-dependent lymphoid tissue, that is, recognition.

On the day of hatching, White Leghorn chickens were divided into five groups. One group was surgically thymectomized, another surgically bursectomized, and a third subjected to both procedures. The following day these birds and an unoperated group were irradiated with 600 r. (conditions of irradiation: 220 kV, 15 m.amp, with 0.25 mm copper filtration at a dose rate, in air, of 45 r./min). In a previous experiment 700 r. was the LD<sub>50</sub> dosage for 2-day-old chickens. All the irradiated animals plus a control unirradiated group were housed together under standard poultry housing conditions.

At the age of 40 days each animal was injected intra-abdominally with 20 mg of crystallized bovine serum albumin (Armour) in saline and 10<sup>6</sup> killed *Brucella abortus* organisms (U.S. Department of Agriculture). Nine days later the birds were bled and killed. Spleen sections from each animal were prepared for staining with methyl green-pyronin<sup>33</sup> and haematoxylin and eosin. Thymus and bursa tissue sections were also stained with haematoxylin and eosin. Assays for antibody to bovine serum albumin were performed by a tube haemagglutination technique using bis-diazotized benzidine linkage of bovine serum albumin to rabbit erythrocytes<sup>34</sup>. Antibody to *Brucella* was assayed by a standard tube bacterial agglutination method. Microimmunoelectrophoresis of sera from each group of animals was performed by the method of Scheidegger<sup>35</sup> with a 0.05 M borate phosphate

Fig. 1. Section of a normal chicken spleen showing the bursa-dependent follicle and surrounding thymus-dependent lymphoid component (haematoxylin and eosin;  $\times$  c. 166)

buffer at pH 8.2, using serum from rabbits hyperimmune to whole chicken serum.

In the chicken spleen there are two distinctly different types of lymphoid tissue. One is seen along the small arteries and arterioles, as sheaths of small lymphocytes or as scattered clusters composed of large and small lymphocytes, lymphoblasts, primitive reticular cells, and frequent mitotic figures. This represents the white pulp of the spleen, the bulk of its lymphoid tissue, and it becomes apparent in normal chickens in the immediate post-hatching period. We found that it was markedly reduced in thymectomized-irradiated and thymectomized-bursectomized-irradiated chickens. Such depletion has been noted previously in chickens subjected to neonatal surgical thymectomy<sup>30</sup> and in birds with testosterone-induced thymic cortical damage<sup>31</sup>. This component was not significantly altered in our other experimental groups. This lymphoid tissue we consider the *thymus-dependent* lymphoid tissue of the chicken.

There is a second type of lymphoid tissue in the chicken spleen, clearly differentiable from the thymus-dependent type both in morphologic appearance and in the time of its development. It is seen as sharply circumscribed round or oval lymphoid follicles (Fig. 1) which seem to be encased by a thin fibrous membrane and which always lie in juxtaposition to a small artery. These follicles bear a striking morphological resemblance to the follicles of the bursa of Fabricius itself (Fig. 2). They are even more clearly separable from the other spleen components when

Fig. 2. Bursa section showing follicular structure (haematoxylin and eosin;  $\times$  c. 166)

stained with methyl green-pyronin because of the cytoplasmic pyroninophilia of the constituent cells (Fig. 3). These structures, in contrast to the thymus-dependent white pulp, develop relatively late in the normal chicken, about the fourth to fifth week of life. Thus, the thymus-dependent tissue is quite well developed by the time the bursa-like follicles are first recognizable morphologically.

These bursa-like follicles were not found in spleen sections of any bird irradiated following neonatal bursectomy or bursectomy-thymectomy, but were consistently present in members of all the other groups regardless of prior manipulation (Table 1). Plasma cells were also consistently absent in the bursectomized-irradiated or bursectomized-thymectomized-irradiated chickens, but were readily found in all the other groups. Thus, we consider the *bursa-dependent* lymphoid system to include these bursa-like lymphoid follicles and the plasma cell system.

Fig. 3. Bursa-dependent follicle in the spleen showing the pyroninophilia of the enclosed cells (methyl green-pyronin;  $\times$  c. 166)

Table 2 gives the antibody titres to bovine serum albumin and *Brucella* in the five experimental groups. None of the animals subjected to both bursectomy and irradiation, and lacking bursa-like follicles and plasma cells in the spleen, developed detectable antibodies to these antigens. In addition, the sera of these birds showed no detectable  $\gamma^M$  (19S) or  $\gamma^G$  (7S) globulins on immunoelectrophoresis, although these bands were regularly seen in the sera of chickens of the other groups (Fig. 4). This is not a quantitative technique, but the

Table 1. BURSA-DEPENDENT FOLLICLES AND PLASMA CELLS IN SPLEENS OF IRRADIATED CHICKENS SUBJECTED TO PRIOR THYMECTOMY AND/OR BURSECTOMY\*

Group	Bursa-dependent follicles	Plasma cells

Thymectomized-irradiated	11/13	13/13
Control-irradiated	14/15	15/15
Control-non-irradiated	15/15	15/15

\* The denominator in each case is the number of animals examined; the numerator is the number of animals in which the structure or cell type was found in any of the several sections from each animal.

Table 2. PRIMARY ANTIBODY RESPONSE OF IRRADIATED CHICKENS SUBJECTED TO PRIOR THYMECTOMY AND/OR BURSECTOMY

Group	<i>Brucella abortus</i>			Bovine serum albumin		
	No. positive*	Mean titre†	S.E.	No. positive*	Mean titre†	S.E.
Bursectomized-irradiated	0/8	—	—	0/8	—	—
Bursectomized-thymectomized-irradiated	0/8	—	—	0/8	—	—
Thymectomized-irradiated	7/12	4.83	1.12	7/12	2.83	0.67
Control-irradiated	16/17	7.30	0.86	14/18	4.18	0.52
Control-non-irradiated	22/22	7.95	0.71	16/20	4.30	0.61

\* The denominator is the number of chickens for which sera were available; the numerator is the number of chickens with detectable antibody.

† The reciprocal of each antibody titre was converted to  $\log_2 + 1$ ; the means and standard errors were calculated using 1 as the value for the negative sera.

Fig. 4. Microimmunoelectrophoresis of sera from bursectomized-irradiated chicken (top) and normal chicken (bottom). The antiserum used was from rabbits hyperimmune to whole chicken serum

results suggest that  $\gamma$ -globulin is absent in the bursectomized-irradiated animals.

Thus, we have 7-week-old chickens, bursectomized and irradiated in the early post-hatching period, which are uniformly agammaglobulinemic, entirely lacking in plasma cells, and incapable of producing detectable antibody to two antigens of different types. Their spleens have no follicular development of the bursa type; their thymuses are morphologically normal (Fig. 5) as is the thymus-dependent lymphoid development in their spleens.

Fig. 5. Normal-appearing thymus of a bursectomized-irradiated chicken (haematoxylin and eosin;  $\times c. 27$ )

It is of interest that significant suppression of antibody-forming ability was also observed in the thymectomized-irradiated birds. Significant depression of antibody responses has occasionally been observed in groups of chickens thymectomized at hatching<sup>21</sup>, but in most instances such birds have had relatively normal antibody levels. The results of the present series suggest that the thymus-dependent tissue in the chicken spleen is sufficiently developed at hatching to respond adequately to antigenic challenge, and that it can continue to do so in the maturing chicken despite the absence of the thymus itself.

These results offer new perspectives not only of the many bursectomy experiments, beginning with the historical work of Glick *et al.*<sup>7</sup>, but also on the recent thymus work.

Generally, the bursectomy investigations, whether the ablation was surgical or chemical, have involved a quantitative suppression of plasma cells, immunoglobulins, particularly the 7S component, and antibody production. Results within series and between series have been quite variable, even allowing for differences in method and strain of chicken. Quite consistent with this picture of residual capacity for antibody production has been the failure to find characteristic morphological changes in the spleens of hormonally or surgically bursectomized chickens, except for the dearth of plasma cells<sup>21,26</sup>.

The effect of bursectomy on the peripheral component of the bursal lymphoid system is seen clearly only in the irradiation model in which the unmistakable bursa-like follicles are eliminated. Since surgical bursectomy alone immediately after hatching does not prevent the development of these follicles, 'peripheralization' of this lymphoid development is apparently well under way at the time of hatching although the follicles themselves are not recognizable morphologically until 4-5 weeks of age.

Treatment of chickens with testosterone propionate during the early embryonic period produces a striking reduction in the bursa-dependent follicles in some of the treated birds. The thymic damage in these birds led Warner *et al.*<sup>21</sup> to associate this reduction or absence of splenic follicles with the influence of the hormone on the thymus. We believe, however, that the splenic follicles they were quantitating were the bursa-dependent follicles, although they did not differentiate these two forms of lymphoid tissue.

The bursa system is brought out in bold relief in another context. As noted earlier, Peterson *et al.*<sup>22</sup> recently showed that the presence of the bursa of Fabricius is necessary for the development of the avian leukosis, visceral lymphomatosis. We might expect, if the concept of the bursa system is valid, to find exaggeration of the bursal follicles in visceral lymphomatosis. This was described ten years ago by Lucas *et al.*<sup>27</sup>, who found that infection of chickens with the virus of avian leukosis resulted in a three-fold increase in the quantity of follicular lymphoid tissue (bursa-dependent tissue in our view). They stated clearly that visceral lymphomatosis did not involve the white pulp (thymus-dependent tissue). They regarded the abnormally proliferating structures of the spleen as ectopic lymphoid structures, although they noted similar structures in normal chickens which were less numerous and less dramatic. The similarity of the structures involved in this form of malignancy and the normal bursal follicle is apparent when Fig. 6 is compared with Fig. 1.

Since the peripheral component of the thymic lymphoid system develops very early compared to the bursal follicles, the role of the thymus has evidently been partially masked in the earlier investigations involving thymectomy immediately after hatching. The variable effects on skin grafts and delayed allergy may well reflect slight strain differences, or even individual differences, in the degree of this peripheral development at the time of hatching. That the chicken thymus, like the thymus of mice, rats, rabbits, and hamsters, has a role in antibody production is shown in the work recorded here in which the peripheral development was reduced by radiation. The response of the thymectomized-irradiated animals

Fig. 6. Spleen section of chicken with early visceral lymphomatosis, showing exaggeration of involved bursa-dependent follicles (haematoxylin and eosin,  $\times c. 166$ )

was significantly lower than that of the irradiated controls. In the postulated two-cell system of antibody production, the thymus-dependent cells apparently provide the recognition mechanism. The bursa system will continue to form plasma cells and produce immunoglobulins when the thymus system is awry, but its efficiency in terms of specificity is much reduced. We believe that this is what we and other investigators have observed in thymectomized mice: appreciable numbers of plasma cells, relatively normal levels of immunoglobulins, but complete loss of capacity for specific antibody response to some antigens, a variable loss of responsiveness to other antigens, and a normal level of reactivity to still others<sup>11,12,15</sup>.

It seems probable that a thymus-type of function is exercised by the appendix of the rabbit, and perhaps by other organs in that and other species. The investigations which demonstrated this function of the rabbit appendix experimentally had as their point of departure morphological similarities of the appendix to the chicken bursa<sup>38-40</sup>. In addition, both of these tissues, as well as the thymus, have a similar embryological origin, either in close association with or directly from the gut epithelium<sup>41,42</sup>. Early removal of the rabbit thymus or appendix or both curtailed specific antibody production<sup>39,40</sup>, but it left intact the plasma cells and a portion of the follicular lymphoid structure in such tissues as the spleen and lymph nodes. Indeed, we<sup>43</sup> observed plasmacytosis in the lymphoid tissues, 'autoimmune' processes, amyloidosis, and at least normal immunoglobulins. It appears that even the thymectomized-appendectomized rabbit retains the mammalian equivalent of the bursal system, and that its locus is another of the gut-epithelium-associated lymphoid organs.

In sex-linked recessive agammaglobulinæmia, the Bruton type, the patients seem to have a loss analogous to that of the bursectomized-irradiated chickens of the present study, as noted earlier. These children have normal thymic morphology and usually have normal numbers of small lymphocytes in the peripheral blood. They recognize 'foreignness', develop delayed allergy, and usually reject skin homografts, though by a slow abnormal process. By contrast, they are almost completely lacking in plasma cells, in true follicles in the lymphoid tissues, and in capacity to form any of the immunoglobulins or circulating antibody. Especially striking in the present context is the failure of development of palatine or pharyngeal tonsils in these patients<sup>44,45</sup>. The human tonsils show close morphological resemblances to the chicken bursa of Fabricius, develop in close association with the epithelium of the gut, and have a similar ontogenetic history, reaching maximum development prior to puberty and then undergoing striking involution.

Thus, it seems more important than ever to test the hypothesis that a mammalian equivalent of the bursa may exist in the palatine and pharyngeal tonsils, or in other gut-epithelium-associated lymphoid tissue such as the intestinal tonsil or sacculus rotundus of the rabbit. This work is in progress.

Many problems, both clinical and basic, take on new perspectives if we consider that there is a two-way division in the lymphoid system. The first, which might be termed 'horizontal', is the distinction between 'central' gut-epithelium-associated lymphoid tissues (the thymus, bursa of Fabricius, appendix, and other tissues to be defined) and 'peripheral' lymphoid tissues, primarily the spleen and lymph nodes. The central tissues are source tissues, using the terminology of Beard<sup>46</sup>, who described the thymus in these terms before 1900. The peripheral tissues are derivative in ontogenetic development, dependent on the central tissues in late embryonic and early postnatal life, but apparently relatively autonomous in the mature organism.

The second division, termed 'vertical', is based on the Bruton type of agammaglobulinæmia and the chicken

model of agammaglobulinæmia just described. It places in one category the bursa of Fabricius (an equivalent unidentified tissue in mammals), the bursa-like follicles of the spleen, nodes, and other tissues (clearly present in mammals), and the plasma cells; and in the other the thymus, other thymus-like central lymphoid tissue, the white-pulp type of lymphoid development in the peripheral tissues, and the small lymphocytes. Functionally, we see this vertical division as immunological recognition and information on one hand, and specific antibody production on the other.

We thank Mr. Melvin Schwartz for his assistance, and Miss Dolores C. Breen for help with the photomicrographs.

# MOLECULAR MECHANISM OF FORMATION OF AN ANTIGEN-ANTIBODY COMPLEX

By DR. A. FEINSTEIN

Agricultural Research Council Institute of Animal Physiology, Babraham, Cambridge

AND

DR. A. J. ROWE\*

Medical Research Council Laboratory of Molecular Biology, University Postgraduate Medical School, Cambridge

IT is usual to describe the formation of antigen-antibody complexes in terms of the lattice theory of Marrack<sup>1</sup>, in which bivalent antibody molecules cross-link determinant sites on antigenic particles or molecules and thus build up a complex network. The (7S  $\gamma$ -globulin) antibody molecule has been described by Oncley<sup>2</sup> as a cigar-shaped particle, of axial ratio 5:1 and length more than 200 Å. In terms of this latter model, it has seemed reasonable to assign the two binding sites to opposite ends of the elongated antibody molecule, and to devise models for the lattice on this basis. Recently, Almeida, Cinader and Howatson<sup>3</sup>, and Lafferty and Oertlis<sup>4</sup>, have attempted to interpret negative-contrast electron microscope pictures of antibody bound to virus particles in these terms.

We have examined pure 7S  $\gamma$ -globulin preparations in the electron microscope (by shadowing and by negative contrast), and complexes of horse-spleen ferritin with rabbit anti-ferritin (by negative contrast). Both rabbit and human pure 7S  $\gamma$ -globulin have been examined, but no differences were observed. Our results suggest a different

mechanism for the building up of antigen-antibody complexes from that described here.

Shadowed pictures of 7S  $\gamma$ -globulin (Fig. 1a) show fields of particles the width (for 90 per cent of the particles in random fields) of which varies between 80 Å and 120 Å, and the thickness (estimated from shadow length) of which is constant at about 34 Å. By negative contrast (Fig. 1b), using a low-temperature method of preparation (to be discussed elsewhere), the particles seen have a low degree of asymmetry, and a maximum linear dimension of about 105 Å. The results from the two techniques are

Fig. 1. Electron micrographs of purified 7S  $\gamma$ -globulin, using the Siemens Elmiskop, examined by (a) shadowing, (b) negative contrast. (a) Rabbit  $\gamma$ -globulin, platinum shadowed at an angle of 15 to one with tobacco mosaic virus as marker; photographed at initial magnification  $\times 3,500$  and an accelerating voltage of 40 kV. (b) Human  $\gamma$ -globulin in 8 per cent sodium tungstoborate, pH 6.2, dried down over holes in carbon film (ref. 9); photographed at initial magnification  $\times 40,000$  and an accelerating voltage of 80 kV.

Fig. 2. (a) Electron micrograph of a mixture of ferritin and antiferritin, with a large excess of the ferritin antigen. Ferritin molecules with antibody bound to them are indicated by arrows. (b) Control ferritin. Microscopy details as for Fig. 1b.

Fig. 3. Electron micrographs of ferritin-antiferritin complexes at proportion near to equivalence, showing cross-linking strands between ferritin molecules. (a) Intact antibody, (b) pepsin-treated antibody, (c) selected areas, with intact antibody. Microscopy details as for Fig. 1b

in good accord, and contradict the picture of 7S  $\gamma$ -globulin as a cigar-shaped particle.

Pictures of ferritin-antiferritin systems at large antigen excess, where no insoluble complex is formed, can readily be explained in terms of one or more such molecules binding without change of shape to the ferritin molecules (approximate diameter 105 Å, by negative contrast) as shown in Fig. 2. The entire absence of cross-linking strands between the ferritin molecules is to be noted. However, at antigen-antibody ratios nearer to equivalence, when a lattice is formed, a large number of rod-like strands, of diameter approximately 15 Å, can be seen cross-linking the ferritin molecules (Fig. 3). If pepsin-treated antibody is used<sup>5</sup>, the strands seen are similar, but show rather less complexity of form (Fig. 3b), presumably owing to the known removal by pepsin of part of the molecule not essential in precipitation. We interpret these strands as corresponding to a 'backbone' feature in the tertiary structure of the antibody molecule, this backbone being non-penetrated by the negative contrast medium. Where these linkages are straight, their maximal length is a little more than 200 Å, which is twice the length of a single, intact antibody molecule; however, it is more usual to see a kink in the linkage, located midway along the length, and the angle of this kink may vary over a wide range (Fig. 4).

We interpret these observations as meaning that in the original antibody molecule the two binding sites are situated fairly close to each other in a compact structure. This compact structure is retained if only a single antigen is bound by the antibody. When, however, cross-linking of antigenic particles occurs, then the antibody molecule 'clicks open' to varying degrees about a 'hinge point' at one end of the molecule, enabling a linkage twice as long as the original antibody molecule to be formed. This theory is illustrated diagrammatically on the right-hand side of Fig. 4.

Fig. 4. Selected areas from electron micrographs to show the various types of linkage observed in ferritin-antiferritin complexes (a-c), and the effect of reduction following pepsin treatment (d). Corresponding to the linkages illustrated, the right-hand side of the figure gives a diagrammatic representation of the 'click-open' theory of cross-linking described in the text. Microscopy details as for Fig. 1b

By using complexes formed with pepsin-treated antibody and, in these precipitated and washed complexes reducing a single disulphide linkage per antibody molecule with mercaptoethanol<sup>6</sup>, the precipitate is completely redissolved. From the solution, pictures of monovalent fragments of antibody bound to ferritin have been obtained (Fig. 4d). These fragments are rod-like, not longer than 100 Å, and show no sign of a kink. This experiment demonstrates that the molecular 'hinge' about which the 'click-open' occurs is almost certainly associated with a disulphide linkage.

In connexion with this theory it should be noted that ferritin, like the viruses, is composed of many identical sub-units and thus identical antigenic sites are repeated within the molecule. There is thus the possibility of the two binding sites of the antibody molecule being satisfied within a single antigen molecule. In other antigen-antibody systems, where this saturation of the two sites by one antigen molecule is not possible, a different form of soluble complex from that observed here (Fig. 2) might occur. It is, however, a general feature of soluble complexes formed in antigen excess that they fix little complement<sup>7,8</sup>. Our theory suggests a simple explanation for

this: the 'click-open' mechanism, which occurs only in insoluble complexes, exposes a part of the 7S  $\gamma$ -globulin molecule which was hitherto masked, and enables it to bind with complement.

Our pictures reveal a distinct tendency for the linkage in insoluble complexes to be through two, rather than one, antibody molecules (Fig. 3). It may be that this double linkage is necessary for the formation of a stable cross-link.

A full account of this work and a more detailed interpretation will be published shortly.

## PORTAL BLOOD SUPPLY TO GLOMUS TISSUE AND ITS SIGNIFICANCE

By TREVOR HUGHES

Department of Anatomy, University of Manchester

THIS article describes a portal system for the flow of venous blood through glomus (chemoreceptor) tissue. The glomera are situated: (1) between the ascending aorta and pulmonary artery (aorticopulmonary glomus tissue); (2) on the arch of the aorta; (3) near the roots of the subclavian arteries (aortic bodies); (4) scattered throughout the cervical and abdominal regions in association with autonomic nerves and ganglia<sup>1-7</sup>. The carotid bodies are not discussed as their blood supply, unlike that of the other glomera, arises directly from the arterial system.

Howe<sup>8</sup> is the only one to have considered the venous drainage of the 'aortic bodies'. He concluded that they were richly vascularized and possessed an arterial supply and a venous drainage. The arterial supply has been investigated many times. The arteries have been described as end-arteries arising from the nearest major vessel.

The usual methods of investigation—microdissection or serial sectioning after injection, or block staining—are time consuming and difficult to interpret. To circumvent these difficulties the present investigator used the well-recognized technique for the investigation of vasa vasorum of injection of Indian ink, with or without gelatin, followed by dehydration and clearing. The blood was washed out with a slightly hypertonic saline solution (1.0 per cent) containing glyceryl trinitrate (1.2 mg/250 ml.). Injection was performed with pulsatile pressure, retrogradely into the descending aorta (160/80 mm mercury) or into the thoracic inferior vena cava (50/20 mm mercury). The cat was chosen as the experimental animal because it is a convenient size and its compact tissue can be recognized in whole-mount preparations<sup>9</sup> by the characteristic appearance of its injected sinusoids (Fig. 1). This was repeatedly confirmed by histology (Fig. 2).

The aorticopulmonary glomus tissue is densest at the base of the heart between the ascending aorta and the pulmonary artery but continues as far as the ligamentum arteriosum. It is also much more intimately associated with the anterior and posterior aspects of the pulmonary artery than has previously been described. Fig. 3 is a

diagram of the typical vascular connexions of a mass of aorticopulmonary glomus tissue. This arrangement was demonstrated in the wall of the pulmonary artery in more than 40 cats. The coronary arteries supply the vasa vasorum of the pulmonary artery and ascending aorta and convey blood to an unusually extensive capillary network specific to the outer half of the media of the main pulmonary artery. Most of the venae vasorum which drain this network enter glomus tissue at the adventitia-medial junction and divide into thin-walled sinusoids in intimate contact with glomus cells (Fig. 4). The sinusoids re-form

Fig. 1. The glomus, outlined by the indian ink in its sinusoids, is on a vein draining the left depressor nerve and to the left of it as it crosses the anterior surface of the left subclavian artery, just above the arch of the aorta of the cat. The vein leaving the top of the glomus was eventually traced to the superior vena cava. The nerve is also indicated by the ink in its vessels. The line is equivalent to a length of 0.25 mm.

Fig. 2. An 8- $\mu$  paraffin section, stained with haematoxylin and eosin, of the glomus in Fig. 1. Parts of the nerve can be seen on the right, top, and bottom, and parts of the injected vein and sinusoids are present. A small nerve bundle enters the glomus from the right and an arteriole occupies the inverted 'V' made by the vein over the top of the glomus. (Line, 0.1 mm)

Fig. 3. Diagram of the vascular connexions of the aorticopulmonary glomus tissue of the cat. The blood in the capillary network probably comes into chemical equilibrium with that in the pulmonary artery lumen by diffusion

veins that eventually drain into the superior vena cava or the coronary sinus.

A portal system similar to that in the aorticopulmonary glomus tissue is present on the anterior and posterior aspects of the arch of the aorta. The capillaries, which penetrate deeper into the media than in adjacent aortic areas, often have small dilatations on their course and appear to radiate to and from a central axis of an artery and vein instead of forming part of a continuous network as in the media of the pulmonary artery. The exact location of these sharply circumscribed capillary areas is variable but appears to correspond to known pressoreceptor areas. The glomera, into which this aortic portal system drains, are more widely distributed on the anterior and posterior surface of the aortic arch than has been indicated in the literature.

Glomera were found on the course of veins draining from autonomic nerves in each of twelve preparations of the mediastinal and cervical tissues. The number of glomera varied from three to eight but this variability may be a reflexion of the completeness of the injection. The right aortic body was found in three cats and the left aortic body in seven; this variability confirms previous findings<sup>8</sup>. The aortic bodies appear to be fortuitous examples

of the random glomera scattered in the mediastinum and are intimately concerned with the venous drainage of the depressor nerves and of the areas of vessel wall innervated by the depressor nerves which are recognized pressoreceptor areas.

The retroperitoneal tissues of eight cats were injected through the abdominal aorta or inferior vena cava. In each, masses of chemoreceptor tissue were seen to be closely associated with autonomic nervous structures and to possess a similar portal venous drainage.

That glomera are supplied by one or more fine arteries is not denied (Fig. 5). The large arteries that penetrate glomus tissue—especially the aorticopulmonary—continue beyond it; they are not the end-arteries implied or depicted by previous investigators. This is obvious in cleared specimens, but would not be so by microdissection or from serial sections. These fine arteries (analogous to the hepatic arteries) probably supply oxygen to chemoreceptor cells, which are thought to have a high metabolic rate. No true arteriovenous anastomoses were seen.

The findings recorded here differ from those of Howe and others by the demonstration of this portal system which allows one to postulate the physiological roles and explain the distribution of these enigmatic structures<sup>6,10</sup>.

The aorticopulmonary glomus tissue is intimately associated with the pulmonary artery and its unique

Fig. 4. The posterior aspect of the pulmonary artery of the cat has been injected, dehydrated, and cleared. The specimen is viewed through the intimal surface. The capillary network drains into a vein which passes to the adventitia-medial junction where it divides into thin-walled sinusoids surrounded by glomus cells. (Line, 0.1 mm)

Fig. 5. An 8- $\mu$  paraffin section (haematoxylin and eosin) of an injected aorticopulmonary glomus of a cat. A large muscular artery passes through the glomus and a fine branch leaves its inferior surface. These branches are comparatively infrequent in serial sections. Several injected sinusoids can be seen surrounded by glomus cells. (Line, 0.05 mm)

capillary network<sup>3</sup>. It is possible that its portal circulation carries to the glomera blood that has reached chemical equilibrium with the mixed venous blood flowing in the pulmonary artery by diffusion across the inner half of the media (area of equilibration; Fig. 3). The chemical environment of the glomus cells would therefore be determined partly by the gradient of diffusion of gases from the blood in the pulmonary artery and partly by the rate of flow of arterial blood into the capillary network. The latter is a measure of the blood pressure and of the vaso-motor tone in the vessels of the system. It is thus possible to reconcile the experimental data of Duke *et al.*<sup>11</sup> with the absence of a vessel from the pulmonary artery lumen to chemoreceptor tissue in the adult animal<sup>12-14</sup>.

The physiological role of a chemoreceptor for mixed venous blood is not evident at the present time<sup>15</sup>. The functioning of this tissue in the foetal animal, suggested by a special branch of supply from the pulmonary artery which closes at birth, indicates that the tissue is concerned with the control of the cardiovascular rather than the respiratory system. This could be its function in the adult.

The glomera associated with the autonomic nerves, ganglia, and pressoreceptor areas are probably protective. These autonomic structures are vital to the animal and an adequate local blood supply must be maintained despite the circulatory readjustments demanded by severe exercise, haemorrhage, or asphyxia. The most logical situation for such a protective chemosensitive mechanism

is on the venous side of the capillaries involved. The anatomical evidence presented demonstrates that the sinusoids of the glomera are part of a portal system carrying effete blood from these capillaries. In the same way the sinusoids of the suprarenal medulla carry venous blood from the suprarenal cortex. Thus the medullary glomus tissue is in a position to 'measure' and increase the blood supply to the cortex. This could explain the puzzling association of the two apparently unrelated tissues. The neurones within the substance of glomus tissue may be part of a local reflex mechanism to bring about local circulatory readjustments.

## AUTORADIOGRAPHIC INVESTIGATIONS OF RNA AND DNA METABOLISM OF HUMAN LEUCOCYTES CULTURED WITH PHYTOHÆMAGGLUTININ; URIDINE-5-<sup>3</sup>H AS A SPECIFIC PRECURSOR OF RNA

By DR. F. G. J. HAYHOE and DR. DENNIS QUAGLINO

Department of Medicine, University of Cambridge

THE pattern of cellular change in cultures of leucocytes from normal peripheral blood, incubated with phyto-hæmagglutinin (PHA), is well established<sup>1-3</sup>, and the metabolic events associated with the process of transformation of numbers of lymphocytes to nucleolated prolymphocytes and then to primitive blast cells during the initial 72-96 h of culture have been further clarified by cytochemical and autoradiographic methods. The periodic acid-Schiff (PAS) reaction, various dehydrogenase reactions, and the use of tritiated thymidine as a specific precursor of DNA have been especially helpful in this regard<sup>4,5</sup>. The increase in cytoplasmic basophilia during transformation suggests that active synthesis of RNA is occurring and that the transforming cell population would be suitable also for investigating the uptake of an appropriate labelled precursor of RNA.

Autoradiographic investigations of RNA synthesis within cells have hitherto been hampered by the lack of labelled precursors which could be specifically incorporated into RNA but not into DNA. Tritiated uridine might be expected to act as a suitable precursor if methylation at the 5-position with subsequent incorporation into DNA of the thymidine so formed could be prevented, or if the process of methylation itself led to a loss of the radioactive label. Uridine tritiated in the 5-position has recently become available from the Radiochemical Centre, Amersham. This compound should lose its tritium label on conversion to thymidine and should therefore serve as a specific precursor of labelled RNA.

We have used this newly available compound, uridine-5-<sup>3</sup>H, to examine autoradiographically the extent of RNA synthesis in lymphocytes, prolymphocytes and blast cells present in cultures of leucocytes from normal peripheral blood, incubated with PHA.

There is much evidence from biochemical and autoradiographic investigations that cells incubated with a radioactive precursor of RNA may rapidly acquire nuclear radioactivity and that when these cells are transferred to non-radioactive medium there is a progressive shift of radioactivity from nucleus to cytoplasm. Whether this shift represents a movement of stable RNA or is a consequence of breakdown of nuclear RNA and diffusion of acid-soluble end-products is still uncertain. Contributions to this problem and references to the relevant literature may be found in several recent articles<sup>6-10</sup>. Although various different strains of cells have been used in the reported examinations they do not include normal human leucocytes stimulated by PHA, and we have therefore made preliminary observations on the movement of label from nucleus to cytoplasm in these cells during a 6-h period of chase following the initial exposure to uridine-5-<sup>3</sup>H and subsequent transfer of cells to non-radioactive medium.

Parallel investigations of DNA synthesis were also performed using tritiated thymidine as precursor, to allow comparison to be made between the respective localizations and time-sequence of uptake of the two labelled compounds. Earlier investigations having shown that prolymphocytes were usually rich in glycogen while blast cells were almost invariably devoid of this substance, the PAS reaction was used in addition to Romanowsky stains to assist in the identification of cells in the autoradiographic preparations and to provide additional data on metabolic relationships during transformation.

At 48 and 72 h when cells with active DNA synthesis were present, the distribution of labelled thymidine was also followed during a 6-h period of chase in non-radioactive medium, in order: (a) to detect the first appearance

Figs. 1 and 2. Nuclear and cytoplasmic grain counts in lymphocytes, polymorphocytes and blast cells from 24-, 48- and 72-h cultures of leucocytes from each of two normal subjects during 6-h periods of chase following incubation for 1 h in uridine-5-<sup>3</sup>H. ○, Lymphocytes cytoplasm; ●, lymphocytes nucleus; □, polymorphocytes cytoplasm; ■, polymorphocytes nucleus; △, blasts cytoplasm; ▲, blasts nucleus

of labelled mitotic figures and thus to assess the duration of the  $G_2$  period of post-synthetic premitotic rest; (b) to determine whether any shift of radioactivity occurred within the cell.

Cultures of leucocytes from the peripheral blood of two normal subjects were set up with PHA in the manner previously described<sup>4</sup>. From each, 3.5 ml. aliquots were removed at 24, 48 and 72 h and incubated at 37° C with uridine-5-<sup>3</sup>H at a final concentration of 0.5  $\mu$ Ci/ml. for a period of 1 h. Further aliquots were similarly incubated with tritiated thymidine at the same concentration and for the same time. From all the uridine-labelled aliquots and from the 48- and 72-h thymidine-labelled aliquots, samples were then aspirated, the cells deposited by centrifugation and smears made on gelatin-coated slides. The remaining suspensions were centrifuged, the radioactive supernatants removed, the cells washed once with fresh medium and finally re-suspended in a further change of fresh medium. Afterwards 0.5 ml. samples were removed at hourly intervals for 6 h and smears made of the centrifuged deposit. All smears were kept in contact with Kodak 'AR10' stripping film for 6 days and after development were appropriately counterstained.

In the uridine-labelled specimens separate nuclear and cytoplasmic grain counts were performed in lymphocytes, polymorphocytes and blast cells and the average scores for each cell type, based on 25-100 cells scored, were calculated. Due allowance was made for the presence of background activity, by appropriate subtraction.

Fig. 3. A polymorphocyte from a 48-h culture after incubation for 1 h in uridine-5-<sup>3</sup>H and subsequent incubation in non-radioactive medium for 5 h. The grain distribution is fairly even throughout the cytoplasm, while there is a strong concentration of radioactivity in the nucleolar region of the nucleus. The two accompanying lymphocytes, one of which has coarse PAS positivity in the cytoplasm, are virtually negative

The results of the uridine-5-<sup>3</sup>H investigations are presented graphically in Figs. 1 and 2. In both cases the patterns of uptake and distribution were essentially similar. The localization of radioactivity was almost exclusively nuclear in all cell-types immediately after incubation in the radioactive medium, whether at 24, 48 or 72 h of culture. Uptake was small in lymphocytes, greater in polymorphocytes and very marked in the blast cells which had appeared in the 48- and 72-h specimens. A conspicuous concentration in the region of the nucleolus was frequently apparent. During the 6-h period of chase there was a tendency for an irregular fall in nuclear grain counts to take place, accompanied by a considerably steeper and more uniform rise in cytoplasmic grain counts especially during the first 2-5 h. The increasing grain density in the cytoplasm was usually fairly evenly distributed, but the nuclear positivity often continued to show local accentuations in the nucleolar areas (Fig. 3). In the 48- and 72-h preparations there was usually a terminal fall in both nuclear and cytoplasmic grain counts. It is clear from the figures that the sum of nuclear and cytoplasmic counts rose during the period of chase. This may have been due to fresh incorporation of label which had not been completely removed during the exchange of medium or which was derived from damaged or degenerating cells. The first of these possibilities appears unlikely in the light of experiments involving

Fig. 4. Grain distribution in lymphocytes and polymorphocytes from a 24-h culture. The lower graphs show findings in cells washed only once, and the upper graphs those in cells washed three times. Symbols same as for Figs. 1 and 2

Fig. 5. Restriction of thymidine label to nucleus in blast cells from a 72-h culture after completion of a 6-h period of chase in non-radioactive medium. A cell in anaphase shows clear localization of activity to the chromosomes

Fig. 6

Fig. 7

Figs. 6 and 7. Distribution of uridine label in blast cells at metaphase

repeated washing of incubated cells in saline prior to their re-suspension in non-radioactive medium for the period of chase. Fig. 4 shows that the intensity and distribution of grain counts in triply washed cells from a 24-h culture did not differ greatly from those in cells washed only once, although the rate of appearance of label in the cytoplasm was slightly retarded. The second possibility is more likely, since release of RNA metabolites from cells in tissue culture and their later re-utilization by other cells has been reported<sup>11,6</sup> and a similar transfer has been observed *in vivo*<sup>12</sup>.

The general distribution and movement of the uridine label show several points of contrast with those of the thymidine label. When the cultures were first set up (0 h) approximately 60 per cent of the lymphocytes took up uridine-5-<sup>3</sup>H, and at 24, 48 and 72 h more than 90 per cent did so. These cells did not show thymidine uptake at any stage. Polymorphocytes were present in the cultures at 24, 48 and 72 h; they invariably showed uptake of uridine at all times, but the great majority failed to incorporate thymidine at 24 h and approximately 70 per cent still showed no uptake at 48 and 72 h. Blast cells were present in the cultures at 48 and 72 h; like the polymorphocytes they were always labelled after incubation with uridine, but between 20 and 30 per cent of them failed to take up labelled thymidine. Furthermore, the thymidine label remained in the nucleus with no appearance of cytoplasmic labelling and no increase in grain density during the whole of the 6-h period of chase at all stages of culture (Fig. 5).

When mitotic figures appeared in the preparations the distribution of uridine label within the dividing cells at metaphase was conspicuously away from the chromosomes (Figs. 6 and 7) whereas the thymidine label, when present, was concentrated on the chromosomes (Figs. 8 and 9). During the 6-h chase of cells incubated with tritiated thymidine, mitotic figures seen at the first and second

Fig. 8

Fig. 9

Figs. 8 and 9. Distribution of thymidine label in blast cells at metaphase

hour were unlabelled, but at the third hour and later most figures showed heavy labelling. This suggests that the  $G_2$  period of rest intervening between the end of DNA synthesis and the onset of mitosis in the cultured cells under these experimental conditions is of the order of 3 h.

The observation that all prolymphocytes and blast cells took up labelled uridine during a 1-h period of incubation would imply that RNA synthesis in these cells is an almost continuous process, the rest periods, if any, being less than 1 h. In this respect the transformed cells from normal human blood appear to resemble HeLa-S<sub>3</sub> cells where RNA synthesis has been found to continue until late prophase and to resume at telophase<sup>7</sup>.

The presence in the 48- and 72-h cultures of 20-30 per cent of blast cells unlabelled after an hour's incubation in tritiated thymidine would be compatible with a duration for the  $S$  period of DNA synthesis in these transformed cells of approximately 2-3 times that of the  $G_1$  and  $G_2$  periods of rest combined.

These preliminary experiments suggest that uridine-5-<sup>3</sup>H may prove to be a satisfactory specific precursor of RNA. The nuclear labelling of many cells which show no tritiated thymidine uptake and are presumably therefore not synthesizing DNA, and the movement of label to the cytoplasm during the period of chase in non-radioactive medium, establish that RNA is being labelled. The absence of chromosomal labelling in cells with strong uptake of uridine during the later stages of culture, when DNA synthesis is also taking place, suggests that DNA is not being labelled by the precursor. Again, if DNA were incorporating a radioactive derivative of uridine-5-<sup>3</sup>H

one would expect some 30 per cent of the prolymphocytes in 48- and 72-h cultures to be much more heavily labelled than the remainder, since only this proportion is synthesizing DNA as judged by parallel experiments with tritiated thymidine. No such discrepancy was observed; the extent of labelling in prolymphocytes was scattered fairly uniformly around the mean.

We have previously shown that accumulation of glycogen precedes DNA synthesis in cells transforming under the influence of PHA (ref. 5). Whether a relation also exists between cellular glycogen and RNA synthesis is less apparent; strong labelling of RNA occurred in cells with much or little glycogen indiscriminately.

We hope that the observations reported here will provide a reference for comparison in future autoradiographic investigations of the behaviour of leukaemic cells cultured *in vitro*.

## A NEW NEUROHYPOPHYSEAL PRINCIPLE IN AN ELASMOBRANCH, *Raia ocellata*

By A. M. PERKS

Department of Pharmacology, College of Physicians and Surgeons, Columbia University, New York, and Nuffield Institute for Medical Research, University of Oxford

AND

PROF. W. H. SAWYER

Department of Pharmacology, College of Physicians and Surgeons, Columbia University, New York

**I**NVESTIGATIONS of the neurointermediate lobe (NIL) of the pituitary of various elasmobranch species (*Squalus acanthias*, *Scyliorhinus caniculus*, *Raia clavata*, *Raia batia*, *Eulania milberti*, *Carcharinus leucas*, *Dasyatis* sp., and *Sphyrna* sp.) by Perks, Dodd and Dodd<sup>1-4</sup> and Sawyer, Munsick and van Dyke<sup>5</sup> have shown that, after allowance for the arginine vasopressin content of U.S.P. standard posterior pituitary powder, the milk ejection, oxytocic and antidiuretic activities approximate to a ratio of 3:1:0.05. This indicates the presence of an oxytocin-like principle (or principles) similar to, but not identical with, oxytocin. In *Squalus acanthias* NIL, Sawyer *et al.*<sup>5</sup> also noted high frog bladder activity.

In the present work, an attempt has been made to purify the oxytocic fraction of the NIL of another elasmobranch species, *Raia ocellata*. 377 freshly caught specimens were dissected at sea. The NILs were dehydrated in acetone, desiccated and extracted in 0.25 per cent acetic acid. The oxytocic agent of the crude extract, which assayed at 18.7 (16.6-21.0) mU/mg acetone dried powder (isolated rat uterus<sup>6</sup>), was shown to be destroyed by 0.01 M sodium thioglycollate, by 0.1 N sodium hydroxide, and by ultra-violet light. The low antidiuretic potency of 1.11 (0.29-4.21) mU/mg (anaesthetized rat assay<sup>7</sup>) was in the expected range, but the rabbit milk-ejection activity<sup>8</sup> of 194 (154-245) mU/mg gave a milk-

ejection/rat uterus activity ratio of 10.3 ( $\pm 1.1$ ), approximately three to four times that of all other elasmobranch species so far investigated (for example, *Squalus acanthias*, Table 1).

Purification of the oxytocic agent was achieved by gel-filtration and ion-exchange chromatography in ammonium acetate buffers. The degree of purification was judged by the increase in oxytocic activity (rat uterus) per mg of total 'peptide' (method of Lowry, Rosebrough, Farr and Randall<sup>9</sup>). 13,635 mU of oxytocic activity contained in 24.3 ml. of crude extract, at 86.9 mU/mg Lowry peptide, were passed in three aliquots through a 3.4 cm  $\times$  91 cm column of 'Sephadex G-25', medium grade. A 5.48 fold purification was achieved. The eluate assayed at 476.9 mU/mg Lowry peptide, and 83.1 per cent of the initial oxytocic activity was recovered. The active eluate was diluted to a specific conductivity of 0.111 mmho/cm and applied to a carboxymethyl cellulose column at pH = 5.0. The oxytocic activity was not adsorbed. The eluate was then brought to pH = 7.1, specific conductivity 0.143 mmho/cm, and passed through a DEAE-'Sephadex' column (A-25, coarse grade). Again, the oxytocic activity was not adsorbed. However, after adjustment of the pH of the eluate to 5.5, specific conductivity = 0.150 mmho/cm, the oxytocic activity was completely adsorbed on a 1 cm  $\times$  23 cm 'CM-Sephadex' column (C-25,

Table 1

Species	Oxytocic activity (rat uterus, without Mg) $\mu$ U/mg acetone dried powder, or $\mu$ U/ml. (95% confidence limits in parentheses)	Ratio of assay values indicated/rat uterus value (without Mg) (S.E. in parentheses)				
		Rat uterus with 0.5 mM Mg	Rabbit milk ejection	Rat antidiuresis	Rat vasopressor	Frog bladder
<i>Squalus acanthias</i> * crude extract $\mu$ U/mg powder	30 (26-34)	1.6 ( $\pm 0.12$ )	2.3†	0.03	0.04	50
<i>Raia ocellata</i> crude extract $\mu$ U/mg powder	18.7 (16.4-21.0)	—	10.3 ( $\pm 1.1$ )	0.059 ( $\pm 0.025$ )	—	—
<i>Raia ocellata</i> purified extract $\mu$ U/ml.	32.8 (30-36)	2.6 ( $\pm 0.2$ )	8.5† ( $\pm 1.0$ )	0.04 ( $\pm 0.004$ )	< 0.02	< 0.46

\* Revised from Sawyer *et al.* (1961), Maine Powder.

† Milk ejection assays carried out against U.S.P. Standard Powder; adjusted for arginine vasopressin content of this standard according to  
 $\frac{\text{Synthetic oxytocin ('Syntocinon')}}{\text{U.S.P. Standard}} = 0.8$

medium grade). Washing with 0.0013 M ammonium acetate, pH = 5.5, specific conductivity 0.135 mmho/cm, did not remove the oxytocic activity, but when the buffer was replaced by 0.02 M ammonium acetate, pH = 6.0, specific conductivity 1.93 mmho/cm, the oxytocic activity eluted in a volume of 336 ml. Final wash with 0.2 M ammonium acetate, pH = 7.0, specific conductivity 16.3 mmho/cm, failed to displace any further oxytocic material from the column. The active eluate contained 80 per cent of the oxytocic activity of the crude extract, but 98.7 per cent of the original Lowry peptide had been removed; the final potency of the peptide was 5,568  $\mu$ U/mg Lowry peptide, which represented a 64-fold purification of the crude extract. Since pure synthetic oxytocin contains about 133  $\mu$ U/mg Lowry peptide, the elasmobranch peptide appears to have only 4.2 per cent of the specific oxytocic activity of oxytocin. The Lowry peptide figure of 133  $\mu$ U/mg for synthetic oxytocin corresponds to a true specific activity of 420  $\mu$ U/mg weight. This suggests that the specific activity of the *Raia ocellata* peptide is 17.6  $\mu$ U/mg weight.

The purified extract assayed at 32.8 (30-36)  $\mu$ U/ml. on the isolated rat uterus without magnesium, and at 86 (77-96)  $\mu$ U/ml. by the same preparation with 0.5 mM magnesium added. The rabbit milk ejection activity was relatively high at 281 (235-337)  $\mu$ U/ml., but the rat anti-diuretic activity assayed at only 1.42 (1.3-1.6)  $\mu$ U/ml. No rat vasopressor activity was found (< 0.8  $\mu$ U/ml.), nor could frog bladder activity be detected (< 15  $\mu$ U/ml.). The ratio of milk ejection to rat uterus activity ( $8.5 \pm 1.0$ ) does not appear to have been significantly altered during purification, since the standard errors for crude and purified extracts overlap one another; the ratio remains more than that for *Squalus acanthias* (Table 1), and more than that for other species so far examined. The absence of any detectable frog bladder activity is also in contrast to the high activity found in crude *Squalus* extracts. Therefore the present evidence suggests that the oxytocic agent of *Raia ocellata* is different from that of *Squalus acanthias* and from the principles found in other elasmobranch species investigated.

The purified extract was lyophilized to a white powder and then twice re-dissolved and re-lyophilized in order to remove ammonium acetate. In four experiments samples of the dry powder were taken up in triple distilled hydrochloric acid (about 6 N), evacuated and hydrolysed at 107°-110° C for 17-24 h. The hydrolysate was analysed on an EEL amino-acid analyser (Evans Electroscelenium, Ltd.) or by high-voltage electrophoresis (Locarte Co., London). Ammonia and ethanalamine were identified, together with the residues of the following eight amino-acids: cystine, tyrosine, serine, glutamic acid, aspartic acid, proline, isoleucine and glycine. The amino-acids were present in approximately equimolar quantities, except for cystine and tyrosine for which there was evidence of some degradation during hydrolysis. The recovery of the amino-acids indicates that the original

peptide had an activity of approximately 17.8  $\mu$ U/mg (rat uterus), a figure in close agreement with that calculated from the Lowry peptide determination. In one analysis only, lysine was also indicated, but it was not in equimolar ratio to the other amino-acids. As the oxytocic activity of the purified peptide was resistant to the action of crystalline trypsin (Sigma Chemical Co.) when the enzyme was at ten times that concentration which completely destroyed a control preparation of arginine/lysine vasopressin ('Pitressin', Parke Davis Co.), it is unlikely that lysine is a constituent of the active principle. In the same analysis the possible presence of ornithine was indicated, but the evidence was inconclusive, and subsequent analyses by high-voltage electrophoresis failed to confirm the presence of either ornithine or lysine, free or in combination, in the final purified extract.

Since the general properties of the unknown peptide resemble those of oxytocin it is reasonable to suggest that those amino-acids present in both occupy the same positions. The unknown would then be the 8-serine analogue of oxytocin:

This analogue is not available and we cannot compare its activities directly with those of the unknown. There are, however, two reasons to doubt that this is the *Raia ocellata* principle. All known analogues with the intact oxytocin ring have frog bladder to rat uterus activity ratios greater than one. None has milk ejection to rat uterus activities greater than three. These ratios for the unknown are less than 0.46 and more than 8, respectively. Comparable frog bladder and milk ejection activities are only known in analogues containing an amino-acid other than isoleucine in the 3-position. This suggests an alternative hypothesis, that the serine may be in the ring, possibly in the 3-position:

An 8-isoleucine fraction is present in the oxytocin-like principle of teleost fishes. At present it would appear that this second sequence, 3-serine, 8-isoleucine oxytocin, provides the best hypothesis for the structure of the *Raia ocellata* peptide, since it fits most closely the chemical properties, the analyses, and our predictions based on structure activity relationships among known analogues. The final establishment of structure must await degradation investigations on the active molecule, and pharmacological comparison of the unknown to synthetic 8-serine oxytocin and 3-serine 8-isoleucine oxytocin, if they become available.

We thank Mrs. Margot Acosta for her assistance, Dr. Derek Hope, Dr. James Levison, Dr. Anne Evans, Capt. H. McLoughlin, Mrs. C. Walker and Dr. G. S. Dawes for their advice and co-operation. This work was supported by a grant from the U.S. National Science Foundation

## NUCLEAR-CYTOPLASMIC INTERACTIONS

By OLE A. SCHJEIDE, RUTH G. McCANDLESS and R. MUNN

Laboratory of Nuclear Medicine and Radiation Biology of the Department of Biophysics and Nuclear Medicine, School of Medicine, University of California, Los Angeles

**I**NDISPENSABILITY of the nucleus for the prolonged continuation of normal cell metabolism has been recognized for many years. Yet, the precise nature of the exchanges which must at some time in the life of the cell occur between nucleus and cytoplasm remains to be fully elucidated.

Pulse tracer investigations such as those carried out by Ficq<sup>1</sup> on frog oocytes, Le Blond and Amano<sup>2</sup> on somatic cells and others on a variety of cells<sup>3,4</sup>, indicate that all or most of the cytoplasmic RNA originates fully labelled from the nucleus. Results obtained from labelled nuclear grafts in amoeba<sup>5</sup> provide further evidence that at least some of the cytoplasmic RNA comes from this source.

Strands of granular materials extending from the region of the nucleolus to the nuclear envelope have been seen in electron micrographs<sup>6,7</sup>. Watson<sup>8,9</sup>, Beams<sup>10</sup> and others provide pictorial evidence for the at least occasional extrusion of such nucleolar material into the cytoplasm. The maximum cytoplasmic basophilia, in many species, corresponds to the moment at which the nucleo-cytoplasmic ratio reaches its peak value.

**Annular 'pores'.** One of the more intriguing features about this apparent wholesale transfer of materials from nucleus to cytoplasm is that in many cells the nuclear 'pores' do not appear to be patent, at least during a major portion of the life of the cell. In the case of the chicken oocyte which has been a primary subject of investigation in our laboratory, two pieces of evidence support this view: (a) in sagittal sections of the 'pores', the true nuclear membrane and the adjacent membrane (which is a part of the endoplasmic reticulum) appear to be pressed closely together but are continuous across the part of the so-called 'pore' which has sometimes been claimed to be patent (Figs. 1 and 3). (b) In tangential cuts across the nuclear membrane (Fig. 2) nearly all the truly bisected 'pores' are observed to contain a single dense and/or osmophilic granule (G) (about 200 Å) positioned in their very centres. (As can be seen in Fig. 1, the granules (G) appear to arrive at the pores from inside the nucleus.)

Wiener *et al.*<sup>11</sup> have provided additional evidence that annular pores, at least in the case of *Drosophila* gland nuclei, do not constitute freely communicating channels between nucleus and cytoplasm. They show that differences in electrical resistance of the nuclear envelope are not related to the numbers of pores in the membrane assayed.

**Passage across the nuclear membrane.** If the nuclear 'pores' are not open across their greater diameters, then how do macromolecules traverse them? One possibility is that the peripheral cores (C), which appear to extend from inside the nucleus to the cytoplasm, may be essentially hollow. The insert in Fig. 2 suggests that this may be possible. However, Feldherr<sup>12</sup> has shown that colloidal gold particles can readily enter the nucleus and do so at the very centres of the annular 'pores' where they are slowed briefly before proceeding inward. It would appear, therefore, that the barriers across the mouths of the 'pores' can be traversed by entities up to 50–60 Å in diameter.

With the hope of gaining more insight into the nature of the materials within the nucleus and the mode of passage of these materials to the cytoplasm, we have

undertaken microscopic investigations on chicken oocytes and cells of the chicken embryo. These cells would appear to be especially favourable subjects because of the rapid growth and differentiation occurring within them. The eggs and embryos were fixed by exposure to 1 per cent osmic acid (pH 7.8) for 2 h, were taken up through 50, 75, 95 and 100 per cent ethyl alcohol steps to propylene oxide and were finally embedded in 'Epon 812'. A 4-week curing period was allowed to elapse prior to cutting (60–90-mμ sections) with a diamond knife and mounting on copper grids coated with collodion and carbon. Staining with lead was carried out according to the method of Karnofsky<sup>13</sup>. The electron microscope used was the RCA model EMU2B.

Although the chromosomes of avian cells appear at interphase to lose almost their basophilia and become invisible or are represented only by a delicately stained reticulum, nucleoli are quite prominent. It would appear, however, that the fine morphologies of these structures are extremely subject to distortion. Following what we consider to be poor fixation, the nucleoli appear to consist of granules. Under possibly better conditions more of the nucleolar sub-structure is revealed to be in the form of vesicles. In Fig. 5 is shown an enlargement from the

Fig. 1. Nucleocytoplasmic interface in chicken oocyte (sagittal section). The nuclear envelope consists of the true nuclear membrane (NM) and the endothelial reticulum (CM). At the periphery of the top 'pore' (P) short cores appear to pass from nucleus to cytoplasm. Two large dense granules (G) can be seen on the nuclear side of two of the pores, and on the cytoplasmic side vesicles (V, V') of various sizes may be seen. At the site marked X, a vesicle appears to be elaborating from the 'pore'. ( $\times 28,875$ )

Fig. 2. The nuclear—or annular—'pores' (P) are here shown in tangential section. Note (in the insert) that the annular cores appear to be either hollow tubes or rows of vesicles. ( $\times 30,675$ )

Fig. 3. Figure illustrating presence in oocyte nucleus (N) of larger granules (G) within vesicles. These are aligned with respect to the nuclear 'pores' (P). ( $\times 30,675$ )

Fig. 4. Oocyte nucleus (N) showing string of vesicles (V) (similar to those comprising 'stacks' in nucleolus, Fig. 5) in association with nuclear membrane. Larger vesicle (K) appears to be forming from smaller ones on cytoplasmic (C) side. ( $\times 48,675$ )

Fig. 5. Extruded nucleolus (N') in 24-h chicken embryo cell. Note folded stack(s) of disks or vesicles (V) and double string of disks extending from base of centre section (V) suggesting that the stacks consist of two coils of such disks ( $\times 40,900$ ). Insert ( $\times 64,900$ ) reveals a central granule in some disks.

matrix of an extruded nucleolus in a somatic cell of a 24-h-old chicken embryo. Several 'stacks' of small (300–400 Å) flattened disks or vesicles, apparently in helical array, can be detected in it. (It is probable that the several stacks represent one or more longer stacks, folded.) From the base of the centre 'stack' two 'strings' of such vesicles appear to emerge and pursue a winding course through the bulk of the nucleolar material (which contains many such vesicles in random orientation). In some cases the presence of a small central granule can be detected (Fig. 5, insert). Brown and Ris<sup>14</sup> have described such 'threads' in nucleoli and have also indicated that the structural units may be hollow spheres (or disks) rather than granules. The significance of the 'stacks' can only be guessed at, as can the presence of organizer material (chromosomal DNA). It is possible that extruded nucleoli, such as this one, are more rapidly fixed due to the absence of a nuclear membrane.

Although a variety of structures may be observed in osmium-fixed nuclei, including (a) dense granules (about 150 Å in diameter) centred in larger vesicles (Fig. 3), and (b) what appear to be clusters of ribosomes (poor fixation?), (c) disks more similar in size to those which comprise the above described nucleolar threads can often be observed close to the nuclear membrane and sometimes appear to be passing through it as in Fig. 4 (note central granules). It is not clear whether or not the nuclear structures other than the small disks of the nucleolus or, indeed, the small disks themselves are variations of—combinations of—artefacts of—the true nature(s) of those substances, but it is recognized that unpredictable swelling of vesicles may take place and that portions of vesicles may condense into granules.

As illustrated in Figs. 1, 6 and 7, passage of vesicular materials from nucleus to cytoplasm appears: (a) to nearly always take place at the site of an annular 'pore', (b) to

involve reduction of the original vesicles into smaller units (we have seen small vesicles), and (c) on the cytoplasmic side of the 'pore' to involve the combination of smaller units (microvesicles) into larger vesicles.

We are not willing to commit ourselves with respect to whether the smaller units pass through the tympanum of the 'pore', whether they traverse the possibly hollow 'cores' (Fig. 2, insert) or whether they 'add' to the cores on the nuclear side provoking the release of a unit from the cytoplasmic side. The pictures of the process in Figs. 1, 6 and 7 suggest that the cores may somehow be involved, at least in some cases.

**Nature of the vesicles.** Many of the vesicles being assembled at the nuclear-cytoplasmic interface assume the morphology depicted in Fig. 8, consisting superficially of a bristled surface and a centrally located rod or sphere. Although the latter are reminiscent of the centrally located granules in the annular 'pores', they do not appear to derive directly from them. In the vesicle that is newly forming (from smaller vesicles elaborating at the 'pore' sites) there is little evidence of a centrally located streak (Fig. 6, SV). The eventual streak is either a dense collection of smaller vesicles or the site of overlapping of the peripheries of larger ones. Especially during assembly stages, the limiting membranes of the emerging vesicles appear to be comprised of at least 2 rows of microvesicles. The 'bristles' of the mature vesicle are only apparent, being manifested by the meeting of the sides of adjacent microvesicles. Although they vary considerably in size and shape, the smallest multi-vesicles, when spherical, measure about 1000 Å in diameter. They appear closely to resemble the 'kinetosomes' described in unicellular organisms by many workers<sup>15</sup>. They possess an inherent

Fig. 6. Oocyte nucleocytoplasmic interface showing elaboration of vesicles (K) from pore sites. Top vesicle appears to be forming from a combination of smaller vesicles each with a central granule. Organelle labelled P may be a polyribosome being formed from a vesicle. Note dark aspect and the presence of a central granule. ( $\times 35,475$ )

Fig. 7. Vesicles (K) being elaborated from 'pore' site at nuclear-cytoplasmic interface in oocyte. ( $\times 18,075$ )

Fig. 8. Nucleic acid-containing multi-vesicles ('kinetosomes'). Note streaks extending along the long axis of the vesicles and the fine surface bristles (probably representing sites where adjacent microvesicles meet). ( $\times 24,525$ )

Fig. 9. This 'kinetosome' (K) in the oocyte (O) appears to be assembling from sub-vesicles (SV) some of which appear to be present at the surface of the follicular cell opposite. There may be connections in the form of narrow tubules between the two cells. ( $\times 24,525$ )

Fig. 10. Vesicles (K) captured in process of being incorporated into yolk granule (YG). Note how vesicles appear to contribute to yolk granule membrane. The vesicles may be both from the surface of the oocyte and the nuclear 'pores'. GM, granular material. ( $\times 16,200$ )

Figs. 11, 12 and 13. Clusters of ribosomes (P) in hen oocyte and chicken embryo cytoplasm (C) which appear to be in a stage of conversion from vesicles. Note centrally located granules (and the darkened interior portions of the polyribosome complexes in Fig. 11). Fig. 11,  $\times 48,675$ . Figs. 12 and 13,  $\times 21,000$

density that is characteristic of nucleic acid (they fail to de-stain markedly following bleaching with  $H_2O_2$ ). They also stand out in contrast to the background following application of periodic acid and silver methenamine. In the oocyte, they probably comprise the substance of the RNA of the yolk nucleus (a large basophilic mass in the cytoplasm where yolk formation first takes place). Similarly appearing vesicles may pass from cell to cell, for example, from follicular cell to oocyte as indicated in Fig. 9. However, even parts of the surface membrane that are quite distant from the surfaces of other membranes may invaginate and give rise to 'pinocytosis vesicles' that closely resemble the nuclear vesicles.

Ehret and de Haller<sup>15</sup> and others have provided circumstantial evidence that 'kinetosomes' act as precursors for cilia of the gullet in *Paramecium*. The presence of 'kinetosome'-like vesicles in the vacuolated mitochondria of this organism suggests that they may play some part in the formation of these organelles as well.

**Vesicles and ribosomes.** Vesicles resembling kinetosomes in morphology contribute to both the internal content and bounding membranes of developing yolk granules in the oocyte of the chicken (Fig. 10). In the chicken, also, similarly appearing vesicles may be involved in the formation of other intracellular organelles<sup>16</sup>.

Although it has been found that the base ratios of the nucleic acids in the nucleolus are similar to the base ratios of the ribosomal and granular materials in the cytoplasm<sup>17</sup>, there exists no evidence that in chicken cells ribosomes pass from the nucleus in the form that they assume in the fixed condition in the cytoplasm. Complexes resembling clusters of ribosomes are detectable in nuclei; however, their increased occurrence therein as a function of what appears to be poor fixation leads to the suspicion that they do not occur naturally in this locus. These considerations suggest that ribosomes (or centres for their formation) are discharged from the nucleus in vesicular form, several thus disguised ribosomes being contained in a given package.

More definitive evidence is available to support this idea. (a) Many of the clusters of ribosomes present in the cytoplasm of chicken cells exhibit centrally located granules which are reminiscent of the central granules seen in 'kinetosomes', and the spacing of the peripheral granules in relation to the central granules often matches the distance observed between granule and 'kinetosome membrane' in the smaller 'kinetosomes' (Fig. 11). (b) Apparent conversion steps of small vesicles to 'ribosome clusters' can be seen in abundance in egg and embryo cells (Figs. 12 and 13).

Recent magnifications of this type of collection of micro-vesicles (which we prefer to term 'kinetosomes' or 'kinetosome-like structures' because these well-known designations summarize our information and speculations regarding their essential character) reveal fibres extending some 500–600 Å from their surfaces which terminate as dense or osmophilic granules (about 200 Å).

## ESTERASES IN SPIDER MITES HYDROLYSING $\alpha$ -NAPHTHYLACETATE

By H. R. SMISSAERT

Laboratory for Research on Insecticides, Wageningen, Holland

**M**ANY populations of the spider mite, *Tetranychus urticae*, have developed resistance to organophosphates. In house-flies it has been found that a 'mutant ali-esterase', capable of organophosphate-detoxification, is a common mechanism of resistance<sup>1</sup>. These mutant ali-esterases have little or no hydrolytic activity to  $\alpha$ -naphthylacetate (NA), if compared with the wild type ali-esterase of susceptible flies<sup>2</sup>. If a similar mechanism of resistance were to occur in mites, this would probably also be reflected by a difference in the rate of NA-hydrolysis. Therefore, the activities of *S*- and *R*-homogenates to this substrate were compared.

The strains used were obtained from and described by Helle<sup>3,4</sup>. He showed the parathion resistance to be mainly dependent on a single genetical factor. Further, Helle applied a procedure of repeated back-crosses between the susceptible (*S*)-strain and the hybrid of *S* and the resistant (*R*)-strain combined with parathion selections after each generation. This procedure tends to eliminate small resistance factors and incidental differences between the *R*- and *S*-strains. The *S*-strain ('Leverkusen normal') and the original *R*-strain ('Systox' or 'Leverkusen RR') are identical with those used by Voss<sup>5</sup> and Voss and Matsu-mura<sup>6,7</sup>. In our work, however, mainly the back-crossed homozygous *R*-strain was used, and in what follows the symbol *R* will be used exclusively for this resistant strain.

Homogenates were made in the cold in all-glass Potter-Elvehjem homogenizers or in smaller ones made of 'Perspex'. The NA-hydrolysis was determined according to the method described by van Asperen<sup>8</sup>. Final concentrations in a typical reaction were:  $3 \times 10^{-4}$  M NA; 0.05 M phosphate buffer pH 7.0; 1 per cent acetone and a single homogenized female per 2 ml. ( $\sim 10$   $\mu$ g/ml.). After a reaction period of 30 min at 27° C, 0.15 ml. of 0.3 per cent tetrazotized di-*o*-anisidine in 3.6 per cent sodium lauryl-sulphate was added per ml. of the reaction mixture. Optical density was measured in a Beckman DU spectrophotometer at 600 m $\mu$ , using a 1-cm cell. A final concentration of  $10^{-5}$  M  $\alpha$ -naphthol gave an optical density of 0.38 after subtraction of the appropriate blanks. Under these conditions the average rate of hydrolysis by homogenates of strain *S* is roughly 3  $\mu$ moles/mg mite-tissue/h. The amount of NA hydrolysed is proportional to the homogenate concentration and the reaction period up to 1 h. In the experiments on the effect of substrate concentration 3.0 per cent acetone had to be used to keep NA in solution at the higher concentrations. Inhibition experiments with the organophosphate diazoxon were performed by pre-incubating the homogenate at 27° C with an excess of inhibitor to realize pseudo first-order kinetics. After a pre-incubation period of 1–5 min, the mixture was diluted at least six times with the substrate solution. The rate of hydrolysis was found to be prac-

Fig. 1. Effect of NA-concentration (Polar co-ordinates) on activity of a total homogenate. For easy comparison of  $S$  and  $R$  ( $\circ$  and  $\bullet$ ) the activities obtained with a particular homogenate were divided by the activity at  $10^{-4}$  M ( $v$ ). The curve drawn is constructed by summation of the lines representing enzymes I, II and III

Fig. 2. Effect of diazoxon concentration (M) on percentage activity (log scale) of a total homogenate after pre-incubation for 1 min at  $27^{\circ}\text{C}$  (note the different scales of the abscissa  $\bullet$  and  $\circ$ )  $\circ$  = 10 min pre-incubation. NA conc. =  $10^{-3}$  M

tically constant, indicating that there was no progress of inhibition during the assay.

A small but highly significant ( $P < 0.001$ ) difference was found between the rates of NA-hydrolysis by homogenates of  $S$ - and  $R$ -females in coupled activity determinations. Similar results were obtained with males and with females in the diapause stage of  $S$  and  $R$  and with females of  $S$  and strain 'Systox'. The activities of  $R$ -homogenates were about 20 per cent lower than those of  $S$ -homogenates. A systematic error was excluded in a series of experiments in which 15 single  $S$ - and  $R$ -females were alternately homogenized and immediately assayed.

This result prompted a further analysis of the enzymes hydrolysing NA under the hypothesis of a causal connexion between resistance and the difference in hydrolytic activity found. Experiments on the influence of NA-concentration on the activity of total homogenates (Fig. 1) revealed the presence of at least two enzymes with different affinities ( $1/K_m$ ) to NA. The effect of

diazoxon concentration on activity demonstrated the occurrence of at least three enzymes (I, II, III) with bimolecular rate constants ( $k$ ) in the order of  $10^7$ ,  $10^6$ , and not more than  $10^3 \text{ M}^{-1} \text{ min}^{-1}$ , respectively (Fig. 2). Further experiments were performed in which the activities of one or two of these enzymes were isolated by irreversible inhibition or heat inactivation. In this way, the  $K_m$  values for NA and the bimolecular rate constants for diazoxon inhibition were determined for three enzymes responsible for at least 90 per cent of the total activity at substrate concentrations between  $3 \times 10^{-5}$  and  $1.5 \times 10^{-3}$  M (Table I). After heat denaturation at  $62^{\circ}\text{C}$ , a single enzyme remained active, with  $K_m \sim 8 \times 10^{-5}$  M and  $k \sim 10^7 \text{ M}^{-1} \text{ min}^{-1}$ . The  $K_m$  value of the least diazoxon sensitive enzyme (III) was determined after irreversible inhibition of enzymes I and II, which was achieved by pre-incubation for 1 min with  $10^{-3}$  M diazoxon. According to the influence of substrate concentration a single enzyme remained active with  $K_m \sim 10^{-3}$  M. The  $K_m$  value of the enzyme with the intermediate diazoxon sensitivity (II) was determined in the following way. First, enzyme I was irreversibly inhibited by 1 min pre-incubation with  $2 \times 10^{-7}$  M diazoxon. Thereafter, the remaining activity, due to enzymes II and III, was determined at different substrate concentrations and the activities of enzyme III at these concentrations subtracted according to the method of Hofstee<sup>8</sup>. The subtractions are made along the polar co-ordinates, which represent constant substrate concentrations, in a  $v$  versus  $v/[S]$  plot (Fig. 1). The line found after subtraction indicated a single enzyme with a  $K_m \sim 10^{-3}$  M. The line drawn in Fig. 1 is obtained by summation of the three lines representing the enzymes with the  $K_m$  values found, while the contributions to total activity at  $10^{-3}$  M NA are estimated from the intercepts with the ordinate in Fig. 2. The deviation of the line from the points might be explained by a small error in one of the values of Table I. However, another

explanation would be a small contribution of a fourth enzyme with a  $K_m$  value even higher than  $10^{-3}$  M.

Surprisingly, apart from the difference in total activity, no significant differences between  $S$  and  $R$  were found for any of the characteristics examined. Therefore, it was not possible to hold either one of the three enzymes responsible for the difference found. It should be noted, however, that the accuracy of these experiments is somewhat smaller than that of those simply comparing normal activities of  $S$ - and  $R$ -homogenates. The experiments on diazoxon inhibition make it unlikely that any of the  $R$ - or  $S$ -esterases examined has hydrolytic activity to this compound. Considering the results, there is little to support the hypothesis that the small difference in total activity between  $S$ - and  $R$ -homogenates is directly connected with the mechanism of resistance.

More recent work showed that the cholinesterase of  $R$  mites is considerably less sensitive to diazoxon and paraoxon inhibition than that of  $S$  mites<sup>9</sup>. For paraoxon inhibition, bimolecular rate constants were about  $10^3$  and  $10^4 \text{ M}^{-1} \text{ min}^{-1}$  for  $S$ - and  $R$ -cholinesterase, respectively. Voss and Matsumura<sup>6</sup> essentially confirmed these results.

This work led to the conclusion that the insensitivity of the cholinesterase is the major factor for resistance. Since it is likely that there are no other resistance factors

Table 1. ENZYMES HYDROLYSING  $\alpha$ -NAPHTHYLACETATE

Symbol	% of total activity at $10^{-3}$ M	$K_m$ (M)	$k$ Diazoxon inhibition ( $\text{M}^{-1} \text{ min}^{-1}$ )
I	55	$8 \times 10^{-5}$	$10^7$
II	15	$10^{-3}$	$10^6$
III	30	$10^{-3}$	$\leq 10^3$

in our back-crossed *R*-strain, it is difficult to explain the significant difference in NA hydrolysis between the two strains. One could think of three possibilities. In the first place, the difference in NA hydrolysis may be caused by a higher activity of the cholinesterase of the *S* strain for this substrate. This possibility, however, is excluded by the fact that eserine concentrations up to  $10^{-6}$  M did not inhibit the rate of NA hydrolysis by *S* homogenates. Moreover, an excess of NA did not inhibit the cholinesterase activity to acetylcholine in these homogenates. Secondly, it could be that the lack of effect of the back-cross procedure is caused by incidental linkage of the NA hydrolysis factor(s) with the cholinesterase factor by the occurrence of, for example, inversions disturbing normal cross-over. However, nothing is known about such chromosomal abnormalities because practically no chromosome investigations have been made on mites. In the third place, there is the interesting possibility of

pleiotropism. This would mean that the alteration of the organophosphate sensitivity of the cholinesterase is caused by mutation of a gene which controls a common factor in the production of this enzyme and the esterase(s) hydrolysing NA. Such a common factor is merely hypothetical but perhaps not unlikely. So far we cannot discriminate between the two possibilities left.

I thank Dr. W. Helle for supplying the strains and for his advice, and Miss L. Herreweynen for her assistance.

## A THEORETICAL BASIS OF ICE NUCLEATION BY ORGANIC CRYSTALS

By V. A. GARTEN and R. B. HEAD

C.S.I.R.O. Division of Physical Chemistry, Chemical Research Laboratories, Melbourne

A CONSIDERABLE number of organic compounds have now been shown to act as ice nuclei<sup>1-5</sup>, the most promising materials being those which can be sublimed without decomposition to form large numbers of particles active at temperatures near 0° C. The activities of  $\alpha$ -phenazine, phloroglucinol dihydrate and metaldehyde lie within the practically useful range for cloud-seeding purposes but activity is not the only criterion of usefulness; it is also necessary to consider photolytic stability and toxicity. The present article is concerned mainly with the possibility of predicting activity, and its effective assessment in the laboratory.

While some workers regard onset temperature to be a measure of activity, it can be seen from Fig. 1 that there is no obvious relation between this and *N*, the number of nuclei/g, active over an extended temperature range. This is because *N* at any temperature depends on the size-frequency distribution of the seed crystals, and on the distribution of active sites. Nucleative power is ultimately a function of the density of active sites; a large particle may thus contain many sites, the most active of which determines the temperature at which the particle will act, whereas small particles may exist that are inactive over the useful temperature range. Although large particles nucleate with less supercooling than small ones, *N* depends essentially on the number of small particles.

Fig. 1 shows the activity of smokes of the important organic nuclei in comparison with silver iodide as measured in the cloud chamber developed by Edwards and Evans<sup>6</sup>. For most organic nuclei the onset temperature is less sharply marked than for inorganic crystals; this may be related to the lower energy of the organic lattice which allows greater freedom of molecular movement at the surface.

The definition of onset temperature is largely a matter of convention; the value depends on the method of preparation and the particle size range. Thus, some particles of phloroglucinol dihydrate have been said to nucleate ice at -2° C, and Fukuta<sup>5</sup> has claimed  $10^4$  nuclei/g for metaldehyde at -0.6° C.

Whether nucleation can be observed at a given temperature will depend on the time one is prepared to wait. If, however, the temperature is lowered at approximately 2° C/min until a point is reached where the rate of nucleation is about one nucleus per sec per  $10^3$ - $10^4$  particles (which is conveniently observed on the microscope cold stage) the following figures are obtained for large particles: (1) phloroglucinol dihydrate, -4.5° C; (2)  $\alpha$ -phen-

azine, -3.5° C; (3) metaldehyde, -5° to -6° C; (4) silver iodide, -4° C.

These figures are the results of many experiments in these laboratories. The samples were prepared by gently crushing recrystallized materials so as not to destroy all the large particles.

The second laboratory method of assessing nucleative activity (*N*), which is done in the cloud chamber, is complicated by many factors which must be rigidly controlled. To obtain reproducible results from aerosols prepared by sublimation, low concentrations of vapour (for example, 100  $\mu$ g/l.) at constant temperature should be swept at standard speeds through a standard orifice by preheated gas into a large reservoir from which aliquot parts may be taken. It is also important to ensure the presence of a sufficient number of small particles by controlled shock cooling. Owing to the low melting-point of organic compounds, particle sizes of up to 2-5 $\mu$  are

Fig. 1. Nucleative activity of some organic smokes compared with AgI. (Each point is the mean of four determinations.) ●, AgI; ○,  $\alpha$ -phenazine; △, phloroglucinol dihydrate; □, metaldehyde

Table 1. CRYSTALLOGRAPHIC AND NUCLEATIVE CHARACTERISTICS OF SOME ORGANIC ICE NUCLEI

Compound	Type	Space group	Unit cell dimensions Å			No. HBGs per 100 Å <sup>2</sup>	Onset temp. °C	Cloud chamber	
			<i>a</i>	<i>b</i>	<i>c</i>			No. nuclei/gram (smokes)	No. nuclei/gram (powders)
Ice			4.51	—	7.35	5.68-6.97	—	—	—
$\alpha$ -Phenazine	1	$P2_1/a$	13.72	5.061	7.088	All planes $\approx 3.0$	-3.5	$10^{11}$ - $10^{12}$	$10^9$
Phenazine- <i>N</i> -oxide	1	$P2_1/a$	14.34	4.6	7.37		-6.0	$10^{11}$ - $10^{12}$	$10^9$
Phenazine-di- <i>N</i> -oxide	5	$P2_1/a$	15.5	3.95	7.83		Below -12.0	Decomp.	$10^7$

Theophylline HCl	6	$P2_1/a$	13.3	15.3	4.5	11.8 (001)	below -17°	—	—
Melamine	8	$P2_1/a$	10.54	7.45	7.25	10.2 (001), 11.8 (100)	-12°	$4 \times 10^7$	$10^3$

usually obtained under laboratory conditions as compared with  $0.1\mu$  for AgI.

A comparison of activities in the cloud chamber at  $-12^\circ\text{C}$  shows that AgI can produce  $10^{13}$  nuclei/g. This is about ten times greater than the number produced by field experiments using smoke generators. Similarly, results obtained with organic crystals in the cloud chamber may not always reflect the activity observed in field tests which depends on the method of generating the smoke. The least effective of the organics shown in Fig. 1 is metalddehyde, for which *N* is four orders less than for AgI, and two or three orders less than for  $\alpha$ -phenazine.

It is now agreed that efficient ice nucleators need not belong to the same crystal system as ice, but it seems unlikely that ice nucleators can be predicted solely from considerations of molecular structure<sup>7</sup>. While for simple organic crystals it is found that good parametric fit (correspondence between unit cell dimensions or their simple multiples) is necessary for high activity, it is not always sufficient. Head<sup>2</sup> was the first to show that hydrogen-bonding is essential for ice nucleation by organic crystals, and the presence of the bonds implies a registry between the compound and the ice. The present concept of fit is thus based on the coincidence of hydrogen-bonding groups (HBGs) at the interface between the ice and the organic crystal. For more complex structures, however, this coincidence is not always immediately obvious from the parameters of the unit cell.

Typical situations leading to activity are thus: (1) single HBGs exposed at the same depth, repeating at multiples (4:1 to 1:1) or sub-multiples of multiples (for example, 3:2) of the ice parameters with a disregistry of < 7 per cent ( $\alpha$ -phenazine, fluorenone I); (2) structures such as phloroglucinol dihydrate, in which the HBG pattern is hexagonal and provides a close fit to the 0001 ice plane; (3) small clusters of HBGs in which the individual members of the cluster have approximately the same spacing as the oxygens in a close-packed ice plane; simple parametric fit is replaced by the probability with which some members of each cluster will coincide with oxygen groups in ice planes (metalddehyde); (4) random HBGs present in optimal concentrations (graphite<sup>8</sup>, chars, polymers).

Arrangements imparting little or no activity are: (5) single HBGs exposed at the same depth with a disregistry of such a value as to allow little coincidence with those of the ice (anthraquinone); (6) HBGs exposed at different levels although parametric fit may be good (theophylline hydrochloride); (7) structures in which parametric fit is satisfactory but in which the number of HBGs presented at the same level is greater than that in ice (dicyandiamide); (8) structures in which disregistry is large and the density of HBGs is too high (melamine); (9) structures in which suitable HBGs are either enclosed

or shielded (hexamethylene tetramine), or blocked by esterification as in cholesteryl acetate, or where they are lacking as in hydrocarbons.

Several examples, demonstrating the different types, are given in Table 1. (References to crystal structures can be found in previous papers.)

Of the good nucleators, type 1 shows an obvious relation between lattice parameters and activity based on a simple pattern of widely separated single HBGs as in  $\alpha$ -phenazine and phenazine-*N*-oxide. The importance of parametric fit is evident from a comparison of these two with the less active phenazine di-*N*-oxide and the almost inactive anthraquinone because disregistry is gradually increasing.  $\alpha$ -Phenazine and anthraquinone, in addition to possessing the same space group, have precisely the same molecular symmetry, showing the same pattern of HBGs in the various planes. The disregistries of ice with respect to  $\alpha$ -phenazine along the *a*, *b* and *c* axes are respectively 2.29, 3.16 and 3.09 per cent, whereas for anthraquinone corresponding values are 14.6, 23.1 and 7.2 per cent.

In phloroglucinol dihydrate, there is an obvious fit of ice to the 100 plane, although it is not evident from the parameters that the HBG pattern is hexagonal (Fig. 2c). While all the hydrate oxygens of the 100 plane of phloroglucinol dihydrate take part in hydrogen bonding, only half the phenolic hydroxyl groups can be so used, since they are presented above the plane of the hydrate rings at such a height that they can take part in a three-dimensional bonding pattern with ice. The other half of them is hidden below the general plane. The structure of phloroglucinol dihydrate is thus unique, and is very different from those of other trimers such as melamine considered by Langer and Rosinski<sup>7</sup>.

An analysis of the HBG pattern of the 111 plane (Fig. 2d) of the  $\alpha$ -isomer of 1:3:5-cyclohexanetriol dihydrate ( $\alpha$ -phloroglucitol dihydrate)<sup>9</sup> suggested high ice nucleative activity, and cloud chamber tests proved this to be correct. This is the first instance of a new highly active organic ice nucleator that has been predicted from theory<sup>10</sup>. Up to  $10^{11}$  nuclei/g were counted at  $-12^\circ\text{C}$ , showing it to possess the same order of activity as phloroglucinol dihydrate and  $\alpha$ -phenazine. The oxygen atoms in the 111 plane show a 1:1 correspondence with those in the 0001 plane of ice, the disregistry being 4.8 per cent. The density of HBGs is thus about 50 per cent greater than in the 100 plane of phloroglucinol dihydrate.

The activity of metalddehyde may be a consequence of parametric fit as suggested by Fukuta<sup>5</sup>. However, a more plausible explanation can be based on the random fit of clusters of four oxygen atoms, which, because of the zig-zag molecular configuration, are exposed freely at the same level. Since the members of the clusters are spaced at about the same distance apart as the oxygen atoms in the 0001 plane of ice, a high degree of coincidence

Fig. 2. Hydrogen bonding patterns of: a, 0001 plane of ice; b, 001 plane of dicyandiamide; c, 100 plane of phloroglucinol dihydrate; d, 111 plane of  $\alpha$ -phloroglucitol dihydrate

occurs at any orientation; thus lattice parameters are of little direct importance here.

In all the active compounds so far discussed, the densities of HBGs (3–4 per 100 Å<sup>2</sup>) are less than those of ice (5–7 per 100 Å<sup>2</sup>). When the density on any plane exceeds this latter figure, nucleative ability disappears and the substance becomes hydrophilic. Dicyandiamide, despite good parametric fit, is thus totally inactive although the HBGs are presented at almost the same level on at least one plane. The pattern is shown in Fig. 2b. The effect of the excess HBGs is evidently to stabilize the denser structure of liquid water rather than that of ice. Similar arguments apply to urea, melamine and hexamethylenetetramine. In isatin, the structure of ice cannot be stabilized because, in addition to high disregistry, the HBGs are presented at various levels. Two Canadian groups<sup>11,12</sup> have recently examined the onset temperatures of amino-acid crystals both as freezing and sublimation nuclei. However, an examination of HBG patterns cannot be made yet since the crystal structures of many of the acids are not known.

It has been shown that slightly oxidized carbons can be made which are highly active, but that it is difficult to keep the number of HBGs within useful limits<sup>8</sup>. Nucleative power has also been claimed for silica gel particles in which the number of hydrophilic sites has been reduced by heat treatment<sup>13</sup>. Whether the efficiency of such materials is due to randomly dispersed HBGs some of which may provide good registry over small areas, or, alternatively, might have to do with microcrystallinity, is still an open question.

In the past, the suggestion has been made that the absence of a molecular dipole moment is required for good nucleative activity<sup>7</sup>. It is seen, however, that when there is good registry between a nucleator and ice, nucleative power is independent of the presence or absence of a resultant dipole moment (compare phenazine-N-oxide with  $\alpha$ -phenazine). Furthermore, melamine with no resultant dipole moment is, in fact, a very poor ice

nucleator. Nor can the high activity of phloroglucinol be attributed to the lack of a resultant dipole moment in the molecule, since it is the dihydrate crystal that shows activity.

There has also been a consideration of an entropy effect<sup>14</sup> which may play an inhibiting part on certain inorganic surfaces, but no good example is as yet known for organic crystals. Inhibition could result from the presence of closely spaced keto, ether oxygen, or tertiary amino groups and thus prevent the formation of the alternating donor-acceptor ice structure in the interface. If, however, such groups are more widely spaced, the ice structure can compensate by arranging its internal bonds in the opposite sense in the gaps so as to preserve the alternating donor-acceptor sequence.

However much the present theory may help in predicting new organic nucleators, the selection of practically useful cloud seeding agents must necessarily also take into account the toxicity and stability of the compounds that have proved efficient in laboratory tests. While the loss of the activity of AgI nuclei is the result of photo-reduction, organic crystals are invariably deactivated by photo-oxidation, the small particles being more prone to attack in both processes. However, neither activity (*N*) nor photolytic stability of organic nuclei appears to be reflected in molecular structure. Thus we have found, by absorption spectroscopy in solution and electron spin resonance investigations in frozen solutions, that the

phloroglucinol molecule is destroyed by a free radical mechanism 3–4 times faster than phenazine. The actual sites of attack in a crystal are decided rather by the ease of accommodation of extra oxygen atoms, which is found to be greater for  $\alpha$ -phenazine than for phloroglucinol dihydrate.

To avoid undesirable pollution of water and food, any new ice-nucleating substances must be tested for acute and chronic pathological effects. Although organic materials may be present in minute quantities only, hazards can arise from selective accumulation of the original materials or their photolytic products, unless biological degradation is complete. Phenazine belongs to a family of bacteriostatic substances to which phenothiazine and amino-acridine are related; its use would be hazardous, since French workers<sup>15</sup> have reported the occurrence of bladder tumours in rats after implantation of pellets containing phenazine. While large doses of metaldehyde produce strychnine-like symptoms<sup>16</sup>, the danger of pollution would be very small because of depolymerization and oxidation to acetic acid. Very little is known about the toxicity of phloroglucinol, but it can be expected to be similar to that of resorcinol, which is a skin irritant.  $\alpha$ -Phloroglucitol, owing to its alicyclic nature and polyalcoholic character, is probably non-toxic.

## ASTROPHYSICS

## Abundance Analysis of a Supergiant in the Large Magellanic Cloud

THE Magellanic Clouds are the nearest extragalactic systems and differ considerably in structure and stellar content from our own galaxy. The chemical compositions of individual objects in the clouds are consequently of great interest. So far some gaseous nebulae have been examined by Aller and Faulkner<sup>1</sup> and found to differ but slightly from corresponding galactic nebulae, but stars have so far been treated by rather general arguments and none has yet been analysed in detail.

Even the brightest stars in the clouds are normally beyond the reach of the Coudé spectrograph of Mount Stromlo Observatory. However, in the hope that a reasonably good spectrum of the brightest member of the Large Cloud, HD 33579 ( $\alpha = 5^h 6^m 1^s$ ,  $\delta = 67^\circ 57'$ , 1950-0, 9.4 mg), could be obtained in exceptionally good atmospheric conditions, an attempt to observe this star was made on December 24, 1963. In order to minimize light losses the slit-width of the spectrograph was increased to  $400\mu$  corresponding to a projected slit-width of  $57\mu$ , which is equal to double the average size of the photographic grain. The resulting loss in resolution is compensated by the high micro-turbulent velocity of 6.3 km/sec.

The attempt was successful and quite a good spectrum of 0.4 mm width and of 10.6 Å/mm dispersion was obtained on a baked Kodak II aO plate. The exposure time was 5 h. The useful range extends from 3700 Å to 4830 Å.

The effective temperature of HD 33579 is not well known. Six-colour photometry by G. E. Kron (private communication) shows that this star is at least 400 degrees cooler than the galactic supergiant  $\alpha$  Cygni unless it is heavily reddened by interstellar absorption, which is unlikely. Assuming  $T_e = 9,170^\circ$  for the effective temperature of  $\alpha$  Cygni (H.-G. Groth<sup>2</sup>) we obtain  $8,765^\circ$  as the highest possible effective temperature of HD 33579. On the other hand, from a consideration of the energy distribution, bearing in mind the effects of electron scattering, it is unlikely that the effective temperature is less than  $7,750^\circ$ , even in the absence of reddening. Unfortunately it was not possible to determine the temperature more precisely.

In view of these difficulties a coarse analysis of the spectrum of HD 33579 was carried out using Wrubel's curve of growth for four different reciprocal temperatures  $\theta = 5040/T = 0.575, 0.600, 0.625, 0.650$ . In all cases the electron pressure  $p_e$  was chosen to satisfy Saha's ionization equation for iron, the only element for which reliable line strengths could be found in two stages of ionization (FeI and FeII). From this, the continuous absorption coefficient (due to Thompson scattering by free electrons and bound-free neutral hydrogen transitions) was calculated. Abundances were determined for the three most important elements of the iron peak group, iron, chromium and titanium.

The  $gf$  values were taken from Corliss and Warner's<sup>3</sup> critical survey for neutral iron and from Corliss and Bozman's<sup>4</sup> monograph for ionized titanium and a few lines of neutral iron. Stellar values derived by Groth<sup>2</sup> in his analysis of  $\alpha$  Cygni were used for ionized iron and chromium.

The results are shown in Table 1. They are normalized to the logarithm of the abundance of hydrogen  $\log N(H) = 23.52$  corresponding to Unsöld's mixture. Likely errors due to the uncertainties in curve of growth fitting are of the order of  $\pm 0.15$  in the logarithm.

Table 1

	0	0.575	0.600	0.625	0.650
$T$		8,765-0°	8,400-0°	8,064-0°	7,754-0°
$\log p_e$		+0.44	0.00	-0.27	-0.42
$\log N(H)$		23.52	23.52	23.52	23.52
$\log N(Fe)$		18.64	18.63	18.61	18.59
$\log N(Cr)$		16.80	16.80	16.79	16.72
$\log N(Ti)$		16.31	16.33	16.13	16.08

As Table 1 shows, the abundances of three elements of the iron peak depend very little on the adopted temperature. This is due to the fact that the metals are predominantly in the singly ionized state and the variation in the continuous absorption coefficient is small.

In view of the fact that the results obtained in an analysis are affected by errors in  $gf$  values, it was deemed advantageous to repeat exactly the same procedure for the galactic supergiant  $\alpha$  Cygni. The equivalent widths of spectral lines were taken from Groth's<sup>2</sup> publication. The results are shown in Table 2 together with Groth's results and Suess and Urey's<sup>5</sup> cosmic abundances, all normalized to  $\log N(H) = 23.52$ .

Table 2

	$\alpha$ Cygni A.P.	Groth's analysis Coarse	Fine	Suess-Urey
$T$	9,163-0	9,163-0		
$\log p_e$	+0.39	+0.76		
$\log N(H)$	23.52	23.52	23.52	23.52
$\log N(Fe)$	18.88	19.10	19.14	18.79
$\log N(Cr)$	16.93	16.10		16.90
$\log N(Ti)$	16.53	16.89	16.65	16.40

A comparison of results shows that Groth's abundances for iron and titanium are higher roughly by a factor of two. There is a large discrepancy for chromium in spite of the fact that Groth's stellar  $gf$  values were used for this element in my analysis.

Although two independent absolute analyses were made for HD 33579 and  $\alpha$  Cygni, the adopted procedure and the  $gf$  values were exactly the same for both stars. The differences in the abundances derived for both stars should therefore be quite reliable. A comparison between Tables 1 and 2 shows that the metal content of the iron peak group is lower in HD 33579 by a factor not exceeding 2. In view of possible systematic differences in equivalent width measurement between the present investigation and that of Groth, one may conclude that the abundance ratio of the metals iron, chromium and titanium to hydrogen in HD 33579 differs from that in  $\alpha$  Cygni by:

$$-0.2 \pm 0.2$$

in the logarithm. This means that the rate of formation of stars and the closely related nucleogenesis may be slightly lower in the Large Magellanic Cloud than in our own galaxy.

The computations on which the foregoing results are based were made partly at Mount Stromlo Observatory and partly at the Royal Greenwich Observatory. I thank the Astronomer Royal for his hospitality. I also thank Dr. B. E. J. Pagel, Dr. A. W. Rogers and Dr. L. Searle for their advice.

## GEOPHYSICS

## A Typical Taurid Meteor Spectrum

INTEREST in spectrophotography of meteors has been fast increasing in recent times<sup>1</sup>. About 500 meteor spectra<sup>2</sup> became available from different countries by 1962. This communication describes the second meteor spectrum from India taken at Waltair at 03 h, 24 min I.S.T. on the night of November 18–19, 1963. Its visual magnitude has been estimated about zero. From the plot of its path on a star map it was found to proceed from the Taurid radiant. The spectrum of this meteor has been photographed on an Ilford 'HP3' film (400 ASA) using a conventional meteor spectrograph with the rotating shutter arrangement. The Contax 35-mm camera used for this purpose carried before its lens ( $f = 50$  mm) a Bausch and Lomb plane replica transmission grating with 200 lines/mm and blazed for 5000 Å. From the duration of the segments produced by the rotating shutter and the plot of the meteor on the star chart, the velocity of the meteor has roughly been estimated at 30 km/sec, which is in close agreement with the mean velocity for the Taurid shower. This appears to be the second best Taurid spectrum in the world, the first one being that secured by Ridley<sup>3</sup>. Dr. Millman mentions (private communication) that there are very few Taurid spectra available in the world.

Table 1. WAVE-LENGTHS AND IDENTIFICATIONS OF THE LINES IN THE SECOND AND THIRD SEGMENTS OF THE SPECTRUM

Wave-lengths	Multiplets identified
3,924.6	FeI (4), CaII (1)
3,968.6	CaII (1)
4,232.4	FeI (3), FeI (152), FeII (27)
4,358.0	CaI (37), MgI (14)
4,461.3	FeI (2), CaI (4), FeI (350)
4,633.1	FeI (554), FeI (822)
5,172.8	MgI (2), FeI (36)
5,253.5	FeI (1), FeI (553)
5,529.5	MgI (9), BaI (2), FeII (55)
5,894.0	NaI (1)
6,349.0	SiII (2)

Nineteen lines have been measured from the present Taurid spectrum (Fig. 1) and eleven wave-lengths have been identified from them. The spectrum can be classified as the 'cY' type, following Millman<sup>4</sup>, the ionized calcium *H* and *K* lines being the strongest features. The lines of MgI, NaI and SiII are also bright, although to a lesser extent than those of CaII in this spectrum. The other lines in the spectrum are very faint and cannot easily be recognized in Fig. 1. From an analysis of Ridley's<sup>3</sup> spectrum, Millman (private communication) found the lines of CaII, MgI and NaI to be the strongest features. This is in close agreement with the general features of the present spectrum. The wave-lengths of the various lines and their identifications are presented in Table 1. The identifications in Table 1 compare well with those of Millman (private communication) for the other Taurid spectrum secured by Ridley<sup>3</sup>, to the extent that both contain different multiplets of CaII, SiII, CaI, MgI, NaI

and FeI, although disagreements do exist in the multiplets identified. The observations recorded here support the already established idea, that meteor spectra from each shower are remarkably similar to each other, having the same general features within the limitations of photographic resolution and emulsion sensitivity<sup>5</sup>.

The excitation potential of the SiII (2) line, equal to 10.03 eV, is the largest recorded in the spectrum. The chance of Taurid spectra being recorded is normally low because of the low geocentric velocity of Taurid meteors. Yet the present spectrum is a specially bright one indicating a large level of excitation. The particular meteoroid producing this spectrum might have had considerable mass to supply the necessary excitation. This is consistent with the suggestion of the two-parameter dependence of ionization and excitation in meteor spectra by Cook<sup>6</sup>, the parameters being velocity and ratio of characteristic dimension to mean free path of an evaporated atom.

### Low-velocity Layer as a Source of the Anomalous Vertical Component of Geomagnetic Variations near the Coast

WITH the development of new techniques and a growing interest in the electrical conductivity of the Earth, the examination of electromagnetic induction in certain types of environment on the Earth's surface has been considerable. Of particular interest is the anomalously large ratio of the variations in the vertical and horizontal geomagnetic components observed near the coast during micropulsation and bay type disturbances. The region of enhancement extends to the landward side of the coast a distance of the order of 100 km, but the extent seaward is at present very poorly known.

The cause of the anomaly at micropulsation frequencies is almost certainly the conductivity contrast found at the land-sea interface.

The source of the bay anomaly is more obscure. In explaining the anomaly found in California, Schmucker<sup>1</sup> has suggested a conductivity distribution that varies

Fig. 1. Spectrum of the Taurid meteor observed at 03 h 24 min I.S.T. on the night of November 18–19, 1963

Fig. 1. Model of the electrical conductivity ( $\sigma$ ) distribution below the coast (after Schmucker)

both with depth and laterally (Fig. 1). Parkinson<sup>2</sup> has independently suggested that the cause of the coastal anomaly lies partly in the upper mantle and cannot be totally generated by the land-sea interface.

In recent years seismology has also found such a lateral inhomogeneity in the mantle. Brune and Dorman<sup>3</sup> have indicated that the average depth to the low-velocity layer below young continents, that is, continental areas other than shield areas (115–310 km), differs from that found below oceans (60–215 km). Differences in the depth of the low-velocity layer are probably caused as much by chemical inhomogeneities as by lateral temperature differences. Allowing for the difference in the temperature distribution under oceans and continents, and ignoring differences of phase and composition on a level surface, the ratio of sub-oceanic conductivity to sub-continental conductivity at a depth of, say, 120 km would be of the order of 1:10, and in the sense required in Schmucker's conductivity model (Fig. 1). With chemical or phase differences as well, it is quite possible that the ratio would be substantially changed, but it is not known, at present, in what sense.

It is important to realize that the bay-type disturbances are affected to an appreciable extent by both the land-sea contact and the mantle differences referred to above. It is to be expected that the position of the mantle conductivity step (Fig. 1) is correlated with the position of the continental slopes, so that where the continental shelf is broad the variations will be of distinctly different character to places where the shelf is narrow. This would account to some extent for the observations of Parkinson<sup>4</sup> that the disturbance vectors bear some relationship to the direction of the nearest deep water.

## OCEANOGRAPHY

### Hot Salty Water at the Bottom of the Red Sea

WATER at a temperature of more than 44° C and salinity exceeding 270 parts per thousand (close to saturation) has been found by the R.R.S. *Discovery* in a small depression below 2,000 m depth in the Red Sea near 21° 17' N., 38° 02' E. Three previous expeditions<sup>1-3</sup> have reported abnormal water in this neighbourhood, but nothing so extreme.

This unusual water was found at *Discovery* station 5580, on September 11, 1964, on the way back from the Indian Ocean, in attempting to re-occupy the *Atlantis II* station 42 (ref. 3). The deep parts of the Red Sea are very irregular, with depth changes of several hundred metres frequently occurring within a few miles. There may be many small isolated basins, though not all of them contain abnormal water.

In order to find the most likely place for sampling, a dan buoy was anchored and a sounding survey made relative to it, within about 5 miles radius (Fig. 1). This revealed two small depressions; one of them, about 1.5 miles across and 200 m deeper than its immediate surroundings, was chosen. Water samples were collected from it, using a pinger as a guide in putting the deepest

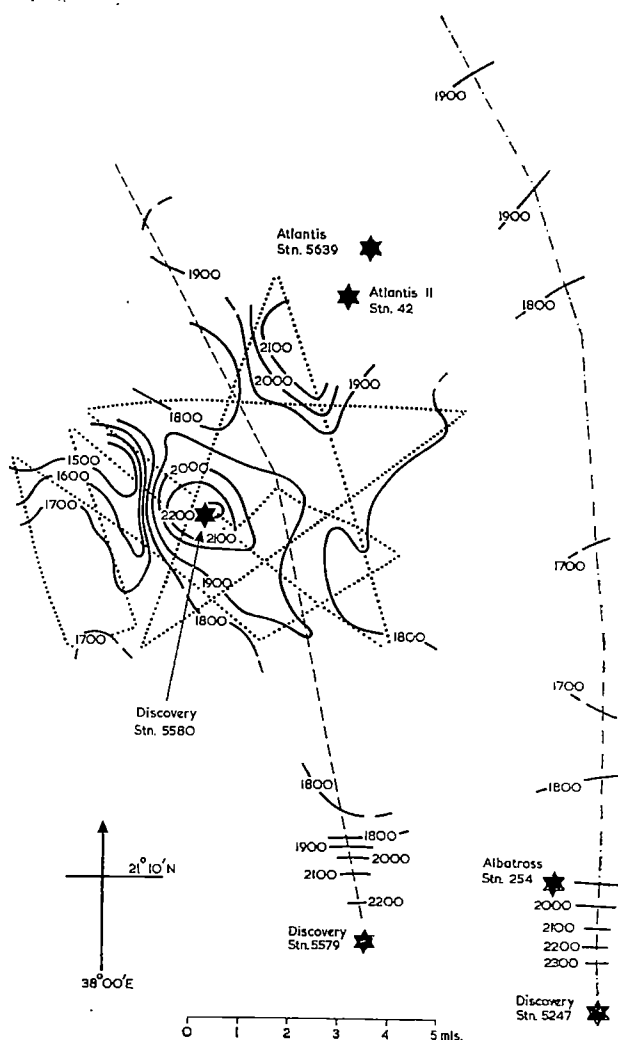

Fig. 1. Bathymetry and station positions where unusually hot salty water has been found. Contours are in metres, corrected according to Matthews's table for Area 51 (ref. 5). —, R.R.S. *Discovery* sounding track, Mar. 1, 1964; —, sounding track, Sept. 11, 1964; . . . . ., sounding track, Sept. 11, 1964, with positions determined by radar from an anchored buoy

bottle close to the bottom. Two casts were made, the first one consisting of 12 bottles spread over 400 m of depth range. The temperatures observed were normal for Red Sea deep water (about 22° C) down to 200 m off the bottom, followed by a sharp increase to well over 40° C in the lowest 150 m. The second cast was arranged to provide more detail in the transition zone and to collect larger samples of the abnormal deep water. Above 35° C we could use only 60° C unprotected thermometers of low-pressure sensitivity since all other available thermometers, protected and unprotected, were off scale.

Temperatures within the hot water were obtained from the unprotected thermometers by applying a pressure correction appropriate to the sampling depth. The latter could be determined by extrapolation from known shallower sampling depths, combined with evidence from the pinger reflexions and the known depth of water.

The vertical profiles of temperature and salinity are shown in Fig. 2. The 'salinities' were measured on a conductivity bridge, after dilution where necessary. The highest salinities required dilution to about one-eighth concentration by weight to bring them on scale. The depths, and hence temperatures, marked † are less certain ( $\pm 15$  m,  $\pm 0.2^\circ$  C) due to greater wire angle and unknown effect of sea floor slope.

The bathymetric contours of Fig. 1, based only on *Discovery* soundings, suggest that the *Atlantis* stations may well have been in a different small basin, and indeed they show a different sill depth and temperature-salinity curve from *Discovery* station 5580. The position of the *Albatross* station 254, shown in Fig. 1, seems inconsistent with the *Discovery* positions, since at *Discovery* station 5247 only a trace of the abnormal water was found<sup>4</sup>.

Preliminary estimates of sulphate, magnesium and calcium, and of the chlorinity: conductivity ratio, suggest that this water is not just concentrated sea-water. Further chemical work is proceeding at the University of Liverpool and at the National Institute of Oceanography.

Speculating on the origin of the abnormal water, it seems unlikely that it can have been formed by evaporation in a shallow sea, as suggested by Charnock<sup>4</sup> for the previously reported abnormal water. More probably it may be due to solution of salt deposits exposed on the sea floor.

The increased density of the concentrated solution would inhibit convection through the transition layer due to heating from the interior of the Earth, and would permit some increase of temperature. The observed temperature gradient in the transition region (nearly  $0.5^\circ$  C  $m^{-1}$ ) is such that the heat loss upwards, with no more than molecular conduction, must be approximately 6 microcalories per square centimetre per second, comparable to the heat flow found coming through the sea

floor itself in regions of high tectonic activity, such as the central part of the Red Sea.

## METEOROLOGY

### Relation between Wind and Pressure at Low Latitudes

INVESTIGATIONS of the relation between wind and pressure in the extra-tropical latitudes show that in the case of large-scale flow the actual wind does not deviate much from the geostrophic wind. Similar investigations at low latitudes have been few. It is generally realized that on account of the small value of the Coriolis parameter at low latitudes one should be cautious in extending considerations based on quasi-geostrophic balance to such latitudes.

Jordan<sup>1</sup> made a comparison between the observed and geostrophic winds from latitude  $13^\circ$  to  $32^\circ$  N. over certain parts of the Pacific and the Atlantic, and found that more than 75 per cent of the observed winds were appreciably sub-geostrophic south of latitude  $20^\circ$  N. Palmer *et al.*<sup>2</sup> found that the monthly mean mid-tropospheric flow in the Central Pacific during a period of steady easterlies was quasi-geostrophic. Worthley<sup>3</sup> examined the relation between observed and geostrophic winds at 500 mb-level over the Pacific based on aircraft reconnaissance reports and rawinsonde data. He found that the median percentage deviation between the observed and geostrophic winds increased from 35 per cent at  $30^\circ$  N. to 87 per cent at  $8.5^\circ$  N. From their investigations over the Equatorial African region, Johnson and Mörth<sup>4</sup> have suggested that with certain types of pressure distributions quasi-geostrophic flow can obtain within a few degrees of the equator. Ramage<sup>5</sup> and Lockwood<sup>6</sup> have recently commented on the subject.

The comparatively weak winds and feeble pressure gradients at low latitudes pose difficulties for a proper observational examination of the relationship between them. In this respect the Indian area of the tropics offers more favourable conditions, since both winds and pressure gradients over this area are stronger compared with the rest of the tropics in certain seasons. We have examined the relationship between the zonal components of the actual and geostrophic winds over the latitude interval  $8^\circ$  N. to  $28^\circ$  N. utilizing the daily radiosonde/rawin data of the following stations which lie approximately along the meridian of  $77^\circ$  E.:

(i) Trivandrum	$08^\circ 28' N.$	$76^\circ 57' E.$
(ii) Bangalore	$12^\circ 58' N.$	$77^\circ 35' E.$
(iii) Madras	$13^\circ 00' N.$	$80^\circ 11' E.$
(iv) Nagpur	$21^\circ 08' N.$	$79^\circ 03' E.$
(v) New Delhi	$28^\circ 35' N.$	$77^\circ 12' E.$

The investigation was made for three lower tropospheric levels (850, 800 and 700 mb) and three upper tropospheric levels (300, 250 and

Fig. 2. Provisional values of temperature and salinity for *Discovery* station 5580

200 mb) separately for the south-west monsoon season (July, August, September) and for winter season (January, February, March) utilizing the data for the period 1961-64. The geostrophic winds ( $u_g$ ) computed from the observed contour height differences for adjacent pairs of stations were compared with the corresponding mean zonal winds ( $u$ ) between the stations, and the ratios  $u/u_g$  were determined for different groups of wind speeds.

The results of this investigation are briefly as follows.

(a) *South-west monsoon season.* (i) Over the Trivandrum-Bangalore sector, the zonal westerlies in the lower troposphere are super-geostrophic ( $u/u_g \sim 1.5$ ); the zonal easterlies in the upper troposphere are sub-geostrophic ( $u/u_g \sim 0.6$ ).

(ii) Over the Madras-Nagpur sector the zonal westerlies of the lower troposphere are nearly geostrophic; the zonal easterlies of the upper troposphere are sub-geostrophic ( $u/u_g \sim 0.6$ ).

(b) *Winter season.* (i) Over the Trivandrum-Bangalore sector, the zonal easterlies are sub-geostrophic, the value of  $u/u_g$  increasing from 0.3 to 0.6 with increase of wind speed from 10 to 25 knots.

(ii) The upper tropospheric zonal westerlies practically geostrophic over the Madras-Nagpur and Nagpur-New Delhi sectors.

Systematic diurnal variations of  $u/u_g$  are also noticed south of lat.  $20^\circ$  N. in both the seasons.

From the equation of motion (neglecting friction):

$$\frac{dv}{dt} = -f(u - u_g)$$

it is readily seen that the nature of the departure of the observed zonal wind from the corresponding geostrophic wind south of latitude  $13^\circ$  N. is such as to give rise to a southward directed acceleration of an air parcel in the lower troposphere in both the seasons. The sub-geostrophic easterlies in the upper troposphere south of  $20^\circ$  N. in the monsoon season will also lead to the same result. These findings are in conformity with the observed<sup>7</sup> meridional circulation.

## Influence of Solar Flare Particles on the General Circulation of the Atmosphere

In the past a few attempts have been made to establish an influence of solar flares on atmospheric pressure, all attempts being limited to a rather small region or even a single station<sup>1</sup>. In the work recorded here I have computed the change in height of the 500-mb level during the first 24 h after a flare for 54 grid-points covering a large portion of the northern hemisphere. The period of investigation is the International Geophysical Year, for which 53 flares well distributed over the whole period have been selected

Fig. 1. Change in height of the 500-mbar level during the first 24 h after the occurrence of a solar flare. Mean of 53 cases. Units: geopotential decametres/day. The dashed circle indicates the zone of maximum auroral frequency

from the Boulder Reports, all flares being of importance  $2^+$  or higher. For flare outbursts which occurred between 12 U.T. and 24 U.T. the next day was taken as 'zero-day'; this was a consequence of the fact that only height data of 00 U.T. were used.

Thus I computed the mean change in height of the 53 cases and plotted the results for the 54 grid-points in Fig. 1. For only five grid-points the mean values are significant beyond the 5 per cent level. Nevertheless, the pattern shows a remarkable regularity with a symmetry with respect to the geomagnetic rather than to the geographic pole.

The main features suggested by the picture are a rise in height of about 2.5 geopotential decametres/day in the region of the geomagnetic axis-pole and a wide region of fall in height (max. 3.5 geopotential decametres/day) coinciding quite well with the auroral zone. Towards the equator of this ring-shaped region again a rise in height seems to occur.

The idea of the auroral zone as the most obvious region of tropospheric reaction to solar particles has already been put forward by Riehl<sup>2</sup>.

More recently Berkofsky and Shapiro<sup>3,4</sup> treated the problem in a theoretical way by assuming a particle-induced heat source having the shape of the auroral zone.

On a similar assumption, but without specifying the height of the heat source (which is actually unknown), I tried to compute the pressure variations in the atmosphere due to such a source of heat.

To perform the calculations, for convenience I have chosen geomagnetic co-ordinates ( $x, y, z$ ). Starting with the formula:

$$\frac{\partial p}{\partial t} = g \int_z^{\infty} \frac{\partial \rho}{\partial t} dz \quad (1)$$

thus neglecting compensating vertical motions, I take into account only the density variations due to isobaric divergence, which according to Schmidt<sup>5</sup> can be written as:

$$\frac{\partial \rho}{\partial t} = -\frac{1}{f^2} \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) \frac{\partial p}{\partial t} \quad (2)$$

where  $f$  is the Coriolis parameter.

Further, let us assume that the heat source  $Q(\vec{x}, y, z, t)$  causes a heating which can be expressed as  $dT B(x, y) F(z)$ . This heating will initiate a density variation at constant pressure:

Fig. 2. Computed pressure change at sea-level (in arbitrary units) due to an atmospheric heat source having the shape of the auroral zone

$$\frac{\partial p}{\partial t} = -\frac{p}{T} \frac{\partial T}{\partial t} = -\frac{p}{T} dT B(x, y) F(z) \quad (3)$$

After integration of equation (3) with respect to  $z$  in (1) and substitution of the result in (2), we obtain a second

approximation for  $\frac{\partial p}{\partial t}$ . By integration of the latter expres-

sion again with respect to  $z$ , but this time from zero to infinity because of the unknown vertical displacements, we arrive at the tendency equation:

$$\frac{\partial p}{\partial t}(x, y)_0 = \frac{g^2 dT F_0}{f^2} \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) B(x, y) \quad (4)$$

Since the auroral zone is almost circular about the geomagnetic pole, we take  $B(x, y)$  independent of  $x$  and assume it normally distributed in  $y$ , so that:

$$B(x, y) = \exp \left( -\frac{(y - y_m)^2}{b^2} \right) \quad (5)$$

where  $y_m$  is the geomagnetic latitude of maximum auroral frequency and  $b$  is the width of the distribution function. Carrying out the differentiation in (4), we find:

$$\frac{\partial p}{\partial t}(x, y)_0 = \frac{2 g^2 dT F_0}{b^2 f^2} \exp \left( -\frac{(y - y_m)^2}{b^2} \right) \left\{ \frac{2(y - y_m)^2}{b^2} - 1 \right\} \quad (6)$$

Now we have to transform  $f = 2\Omega \sin \varphi$  into  $(x, y)$  coordinates. From a simple calculation in a spherical triangle follows:

$$\sin \varphi = \cos \Delta \sin y + \sin \Delta \cos y \cos x \quad (7)$$

with  $\Delta$  is the angular distance between the geographic and the geomagnetic pole ( $\Delta = 11^\circ 30'$ ).

Combining (6) and (7), we obtain:

$$\frac{\partial p}{\partial t}(x, y)_0 = \frac{g^2 dT F_0}{2 b^2 \Omega^2} \exp \left( -\frac{(y - y_m)^2}{b^2} \right) \left\{ \frac{2(y - y_m)^2}{b^2} - 1 \right\} \quad (8)$$

$$\sin^2 y \cos^2 \Delta + \cos^2 y \sin^2 \Delta \cos^2 x + \frac{1}{2} \sin 2y \sin 2\Delta \cos x$$

From equation (8) I have drawn a tendency map (Fig. 2) in arbitrary units (without knowing the height and vertical stratification of the heat source it is impossible to

evaluate  $F_0$ ), for  $y_m = 67.5^\circ$  N. (geomagnetic latitude) and  $b = 15^\circ (= 1.67 \times 10^8$  cm). Compared with Fig. 1 it may be concluded that probably this manner of theoretical approach is able to explain the principal features of the observed pattern.

In order to obtain a better insight into the mechanism involved, this study is now extended to other levels than 500 mb, while the duration of the influence is also examined. Special attention is given to stratospheric temperatures in order to establish the height of the diabatic heat source. From the patterns shown (Figs. 1 and 2), one may conclude that one of the possible consequences of the particle-induced disturbance for the general circulation is the development of wave numbers one and two. From their dynamical study, Berkofsky and Shapiro came to the same conclusion<sup>4</sup>.

After a solar particle invasion the pressure gradient over the east Atlantic changes in such a way as to stimulate a south-westerly current. Indeed, during the recent period of high flare frequency (1946–1960) south-westerlies have been much

more frequent than usual over this area.

Finally, as a rather speculative comment, the phenomena described in this communication may be of great importance for the establishment of solar-climate relationships.

I thank Dr. F. H. Schmidt for his stimulating interest and the many valuable discussions.

## Tattering of Flags under Controlled Conditions

THE rate of tatter of standardized textile flags has been used as a cheap and convenient index of exposure to wind<sup>1-3</sup>, but no attempt has been made to determine whether, or to what extent, water in the flag affects the rate of tatter. This effect has been measured to determine whether loss in dry matter may be substituted for loss in area as a measure of tatter, and whether it is acceptable to remove the protective fray from a used flag in order to re-expose it on its original site for further periods.

Flags with initial free-flying area  $9 \times 14$  in. were prepared by placing 2 oz. madapollam (D.T.D. 343) between sheets of glass illuminated from below, and by tracing outlines parallel to the weft and warp. Threads were then shredded and cut from the material until only the appropriate outline remained. Air-flow of known velocity was generated by controlling the size of outlet and speed of centrifugal fans; flags were mounted in the air-flow and measurements made of losses in area and dry matter over periods of  $1\frac{1}{2}$ –12 h. The outline of solid weave was recorded after the protective fray had been removed and the residue weighed. Flags were thus exposed for successive periods, the loss in area and dry matter being recorded each time as a percentage of the area and weight of free-flying material in the initial flag. The mean of percentage reduction in area and percentage weight loss of dry flag was adopted as the most accurate measure of tatter, and for each flag, means over successive periods were averaged to give a long-term measure.

Some flags were exposed dry; others were kept saturated throughout. Fig. 1 shows that for dry flags a linear

Fig. 1. Flags were exposed over eight successive 90-min periods. For each period a mean was calculated of losses in dry-weight and area as percentages of free flying material in the initial flag. Readings were averaged over successive periods and the resultant means are shown in relation to windspeed

relationship holds between percentage tatter ( $y$ ) and windspeed ( $x$ ), the regression line being given by

$$y = -0.256 + 0.136x$$

This linear regression contrasts with an exponential relationship for saturated flags (a linear relationship  $\log y = -0.134 + 0.024x$  between the logarithm of percentage tatter ( $y$ ) and windspeed ( $x$ ) shows that this relation is exponential). When percentage tatter is plotted against run of wind, linear and exponential relationships are again evident.

The regression equation  $y = -0.256 \pm 0.136x$  indicates that, theoretically, winds down to 1.882 m.p.h. cause tattering when flags are dry. In practice flags must fly freely before tattering can occur, and in the case of wet flags of  $9 \times 14$  in., winds of 10 m.p.h. are necessary to allow them to fly freely. Once flags are supported by the air flow, however, they tatter in accordance with the relationships  $y = -0.256 + 0.136x$ , and  $\log y = -0.134 + 0.024x$ , for dry and wet flags respectively.

These results indicate that under dry conditions the madapollam flag gives a reasonable measure of run of wind and of mean windspeed. Unfortunately, unless continuous records of rainfall and windspeed allow elimination of excess tatter due to water in the flag at high windspeeds, it is evident that the use of flags where high winds accompany rain must exaggerate variation in exposure to wind. If no correction factor for rainfall can be applied to field measurements, no valid comparison of run of wind or mean windspeed can be made between sites or between non-contemporaneous exposures.

Water in the flag is unlikely to exaggerate exposure to wind at windspeeds below 30–35 m.p.h., but if windspeeds exceed this level during periods of rain, and if no correction

factor for rainfall can be established, exposure will be exaggerated. Consequently, the use of flags as indicators of exposure in biological studies will be acceptable only where a measure of integrated effects of wind and rain is sought, and where single and integrated biological effects may be described by regression lines similar to those for wet and dry flags. The madapollam flag cannot be regarded as a physical anemometric instrument; it gives a measure of exposure, but only as a function of the interaction of wind and rain with the particular fabric used.

## CHEMISTRY

### Preparation and Melting Point of Di-2-phenylethylmercury

THE preparation of di-2-phenylethylmercury (I) has been reported by Criegee, Dimroth and Schempf<sup>1</sup>, and Nerdel and Makower<sup>2</sup>. Criegee *et al.*<sup>1</sup> prepared (I) by the reaction of 2-phenylethylmagnesium chloride (II) with mercuric chloride and obtained (I) as an oily product, the identity of which was confirmed by its reaction with mercuric chloride to form 2-phenylethylmercuric chloride (III) (85 per cent) and with mercuric acetate to form 2-phenylethylmercuric acetate (35 per cent). The melting-point of (I) was not recorded. Nerdel and Makower<sup>2</sup>, using a similar method (reaction of 2-phenylethylmagnesium bromide (IV) with mercuric chloride), obtained a sample of (I) which crystallized at  $-40^\circ$ .

In an attempt to clarify these results, the preparation of (I) was carried out by three methods. The first method was a two-stage synthesis in which (II) (0.140 mole) reacted with mercuric chloride (0.154 mole) to form (III), m.p.  $164^\circ$  (Criegee *et al.*<sup>1</sup>: m.p.  $165^\circ$ – $168^\circ$ ), and then (III) was caused to react with (II) to form (I). The second method was also a two-stage synthesis in which (IV) (0.11 mole) reacted with mercuric bromide (0.12 mole) to form a 2-phenylethylmercuric bromide (V), m.p.  $169^\circ$  (Hill<sup>3</sup>: m.p.  $169^\circ$ ), and then (V) (0.05 mole) reacted with (IV) (0.10 mole) to form (I). The third method was a one-stage synthesis in which (IV) (0.12 mole) reacted with mercuric bromide (0.04 mole) to form (I). The symmetrical mercurial, (I), was obtained from all three syntheses as an oily product with approximate m.p.  $-44^\circ$ , which is comparable to the melting-point obtained by Nerdel and Makower<sup>2</sup>.

I thank E. J. Young for assistance with the experimental work.

### Assignment of the Infra-red and Raman Bands of Liquid Water

THE assignment of the fundamental vibrational frequencies of water vapour is well established<sup>1</sup>: 3,651.7 cm<sup>-1</sup>  $\nu_1$  symmetric stretch, 1,595.0 cm<sup>-1</sup>  $\nu_2$  bending and 3,755.8 cm<sup>-1</sup>  $\nu_3$  antisymmetric stretch, of symmetry species  $a_1$ ,  $a_1$  and  $b_1$  respectively for molecular symmetry  $C_{2v}$ .

The assignment in the liquid phase is still not properly understood; the bands become very broad in both infra-red (IR) and Raman (R) spectroscopy.

Table 1 shows how the frequencies change from gas phase to liquid phase, and the assignments for liquid water made by previous authors.

	$\nu_1$	$\nu_2$	$\nu_3$
Gas	3652	1595	3756
Liquid	3450	1640	3615

Table 1

The dotted arrows in Table 1 represent the conclusions of Fox and Martin<sup>2</sup> and the solid arrows the assignments of Schultz and Hornig<sup>3</sup> and Walrafen<sup>4</sup>.

If Fox and Martin (Table 1) are correct, the origin of the 3,615 cm<sup>-1</sup> Raman band must be determined; if Schultz and Hornig are correct, the absence of a band corresponding to  $\nu_3$  near 3,615 cm<sup>-1</sup> in the infra-red spectrum must be explained. For a molecule without a centre of symmetry the rule of mutual exclusion is not applicable and there should be a maximum of correspondence between infra-red and Raman spectra.

The assignments of the Raman bands given by Walrafen, and Schultz and Hornig, are based on polarization data. Schultz and Hornig show that the depolarization ratio,  $\rho$ , for the bands at 1,640, 3,225 and 3,450 cm<sup>-1</sup> respectively is considerably less than 6/7, and, therefore, the major portion of the intensity of these bands must arise from symmetric vibrations. For the 3,615 cm<sup>-1</sup> band,  $\rho = 0.60$ , which is still rather less than  $\rho = 6/7$  expected for  $\nu_3$ . Schultz and Hornig attribute the discrepancy between 0.60 and 6/7 to overlap by the strong 3,450 cm<sup>-1</sup> band. However, if  $\rho$  were 6/7 at 3,615 cm<sup>-1</sup>, the band would not necessarily arise from an asymmetric vibration, since even symmetric vibrations may give  $\rho = 6/7$ . In our opinion, this evidence in favour of the assignment of the 3,615 cm<sup>-1</sup> band to  $\nu_3$  is extremely weak.

In general, in infra-red and Raman spectroscopy, the absolute band intensity arising from a symmetric vibration is a minimum and a maximum, respectively. The converse is true for antisymmetric vibrations. In the gas phase, the infra-red spectrum shows  $\nu_1$  very weak relative to  $\nu_3$ , and in the Raman spectrum the converse is true. It is, therefore, reasonable to suppose that in the liquid the 3,450 cm<sup>-1</sup> infra-red band is mainly  $\nu_3$  and that the 3,450 cm<sup>-1</sup> Raman band is mainly  $\nu_1$ . The 1,640 cm<sup>-1</sup> band (IR and R) is undoubtedly  $\nu_2$  from considerations of both frequency and polarization data. Assignment of the 3,225 cm<sup>-1</sup> band to  $2\nu_2$  in Fermi resonance with  $\nu_1$  is well supported by its polarization, and variation of intensity with temperature<sup>5</sup>.

We prefer the overall assignment of Fox and Martin (Table 1) and give our full assignment in Table 2. We

believe that the best assignment for the 3,615 cm<sup>-1</sup> band is a combination, 3,450 +  $\nu_H$ , where  $\nu_H$  is the stretching vibration of a hydrogen bond. The value of  $\nu_H$  is about 180 cm<sup>-1</sup> (there is some doubt about the exact value, but it is between 160 and 200 cm<sup>-1</sup>). This combination band would be expected to have a low intensity and, therefore, we postulate a second Fermi resonance between  $\nu_1$  and this band; that is,  $\nu_H$  must have the same symmetry as the 3,450 cm<sup>-1</sup> component of the combination. The result is an  $a$ -type band. This assignment explains the absence of the 3,615 cm<sup>-1</sup> band in the infra-red spectrum, because the main band at 3,450 cm<sup>-1</sup> is now  $\nu_3$ , symmetry  $b_1$ , so that Fermi resonance is not allowed. The same reasoning applies to the 3,225 cm<sup>-1</sup> ( $2\nu_2$ ) band, and consequently the 3,450 cm<sup>-1</sup> infra-red band appears with only a very slight asymmetry on the low-frequency side because of a residual intensity from  $2\nu_2$ .

The assignment we propose for liquid water is supported by several other pieces of experimental evidence. Various authors (see ref. 5) have investigated the infra-red spectrum of water in different solvents. The separation  $\Delta\nu$  between  $\nu_1$  and  $\nu_3$  is found to vary with the dielectric properties of the solvent. In carbon tetrachloride  $\Delta\nu$  is 95 cm<sup>-1</sup> while in dioxan it is only about 70 cm<sup>-1</sup>. In pyridine only one band is observed, and this has been interpreted as  $\nu_1$  and  $\nu_3$  having the same frequency. However, no polarization investigations have been made on these solutions and assignment of the two bands to more than one hydrogen-bonded species of water molecule is not excluded. Walrafen<sup>4</sup> has examined the variation of intensity of the 175 cm<sup>-1</sup> Raman band as a function of temperature and of electrolyte addition. Our results and those of Schultz and Hornig<sup>3</sup> indicate that as electrolyte is added the 3,615 cm<sup>-1</sup> and 175 cm<sup>-1</sup> bands decrease in intensity. When the temperature is raised the 3,615 cm<sup>-1</sup> band intensity appears to increase slightly<sup>3</sup> while that of the 175 cm<sup>-1</sup> band decreases<sup>4</sup>. However, this anomaly in the temperature effect is not necessarily in disagreement with our assignment, because a change in the Fermi resonance conditions with temperature could more than compensate for the temperature coefficient of the 175 cm<sup>-1</sup> band.

We thank Dr. B. A. Pethica for his advice.

### Mechanisms of Reactions in the Acenaphthene Series. Migration of *t*-Butyl, and Disproportionation

By a variety of Friedel-Crafts reactions, using *t*-butyl chloride and acenaphthene, we have synthesized and orientated 1-, 2- and 3-*t*-butylacenaphthene<sup>1-3</sup>. A mechanism is now proposed to explain the *t*-butylation of acenaphthene and the novel migrations of the *t*-butyl group observed when *t*-butylacenaphthenes were treated with 0.15 mol. of aluminium chloride at 45°:

Table 2

Phase	cm <sup>-1</sup>	Symmetry species	Assignment	Observed in IR or R
Gas	1,595	$a_1$	$\nu_2$	IR
	3,652	$a_1$	$\nu_1$	R
	3,756	$b_1$	$\nu_3$	IR
Liquid	1,640	$a_1$	$\nu_2$	IR, R
	3,450	$a_1$	$\nu_1$	R
	3,450	$b_1$	$\nu_3$	IR
	3,225	$a_1$	$2\nu_2$	R
	3,615	$a_1$	$\nu_1 + \nu_H$ or $\nu_3 + \nu_H$	R

*t*-Butyl chloride is very reactive in Friedel-Crafts reactions with acenaphthene, only a small amount of aluminium chloride being required. It is probable that ionization of *t*-butyl chloride is induced by the catalyst, and that *t*-butylation of acenaphthene follows the procedure of electrophilic aromatic substitution, with attack by the relatively stable *t*-butyl carbonium ion. Reaction mixtures tend towards equilibrium, the thermodynamically most stable 2-*t*-butyl derivative, with least free energy, being formed at the expense of the less stable 1- and 3-*t*-butyl compounds. It was surprising that the main product, using aluminium chloride, was 2-*t*-butylacenaphthene, even at reaction temperatures of  $-10^{\circ}$  to  $-5^{\circ}$ . The greater thermodynamic stability of the 2-isomer could be partly due to the less sterically hindered nature of this position in acenaphthene.

Unlike aluminium chloride, ferric chloride does not cause migration of the *t*-butyl group in the acenaphthene nucleus, and a controlling factor is probably the rate of reaction. 1-*t*-Butylacenaphthene predominates at reaction temperatures of  $10^{\circ}$ – $15^{\circ}$ , whereas at  $45^{\circ}$  the 3-isomer is the main product formed. In the presence of ferric chloride, further *t*-butylation of the 1-isomer at  $10^{\circ}$ – $15^{\circ}$  gave, by ortho substitution, 1,6-di-*t*-butylacenaphthene, and thence 1,3,6-tri-*t*-butylacenaphthene, also derived directly from 1- or 3-*t*-butylacenaphthene.

Regarding electron-availability, acenaphthene is a more reactive nucleus than benzene<sup>4</sup>. In electrophilic attack on acenaphthene, the electron-releasing inductive effect of the ace-bridge would activate both benzene rings, but in considering monosubstitution, it is convenient to represent attack to give the more stable intermediate carbonium ions of the type shown, where the positive charge is located at the carbon atom nearest the activating group:

The above represent only contributory structures of the complex hybrid carbonium ions formed by attack at positions 1 and 3, with the positive charge developing and being dispersed in the ring. The analogous carbonium ion formulated by attack at the 2-position comprises less-stable configurations. In the case of acenaphthene, any stabilization of carbonium ions by contributory hyperconjugated structures is probably a minor factor. Thus, at low temperatures and with a catalyst of moderate strength, the Friedel-Crafts *t*-butylation of acenaphthene follows the normal orientation, without cleavage of *t*-butyl, and loss of a proton from the respective hybrid carbonium ions affords the *t*-butylacenaphthene.

The literature contains no reference to group migration in the acenaphthene series. Baddeley<sup>5</sup> suggested that in alkylbenzenes, an intramolecular rearrangement occurred, the group migrating without leaving the sphere of influence of the molecule. The relative merits of intramolecular and intermolecular migration of radicals in cymenes were discussed by Allen, Alfrey and Yats<sup>6</sup>. While we have an open mind on intramolecular rearrangement mechanisms concerning migration of methyl groups, in our case, we favour a de-alkylation-re-alkylation mechanism, with formation of a *t*-butyl carbonium ion.

Formation of the carbonium ions derived by 1- and 3-attack on acenaphthene involves a reversible reaction; in the presence of aluminium chloride, the liberated *t*-butyl carbonium ion yields 2-*t*-butylacenaphthene, probably by loss of a proton from a very unstable carbonium ion, of which one contributory structure of the hybrid could be represented as:

The thermodynamic stability of 2-*t*-butylacenaphthene would cause it to persist.

A similar mechanism for the disproportionation reactions, which occur when any of the three mono-*t*-butylacenaphthenes is heated with a little aluminium chloride at  $45^{\circ}$ , would involve prior addition of a proton, probably arising from the presence of a little hydrochloric acid: a chain reaction would then ensue. Even 2-*t*-butylacenaphthene accepts a proton, and the *t*-butyl carbonium ion is liberated; this then attacks 2-*t*-butylacenaphthene at the other meta position, and subsequent loss of a proton gives 2,5-di-*t*-butylacenaphthene: thus a continuous interchange of proton and *t*-butyl carbonium ion occurs. 2,5-Di-*t*-butylacenaphthene forms a complex with aluminium chloride, and it may be the most basic, and is certainly the most stable, of the mono- and di-*t*-butylacenaphthenes. It is isolated readily from 1-, 2- and 3-*t*-butyl- and 1,6-di-*t*-butyl-acenaphthene, by treatment with 0.15 mol. of aluminium chloride in boiling carbon disulphide.

The work represents pioneer orientation in the acenaphthene series. Interest in acenaphthene, a 'cinderella' among coal-tar hydrocarbons, has been aroused by the recent development of commercial dyes for polyester fibres, of excellent fastness properties.

## BIOCHEMISTRY

### Effects of Antibiotics on Chromosomes of Cultured Human Leucocytes

PENICILLIN and streptomycin have been commonly added to growth media used in the culture of human leucocytes for cytogenetic analysis. Since the literature on human cytogenetics is increasing rapidly, largely through the use of these techniques, it seemed appropriate to examine any possible cytological effects of antibiotics *per se* on cultured human leucocyte chromosomes or on the mitotic index.

The antibiotics used were buffered penicillin G potassium for injection, streptomycin sulphate for injection, chloramphenicol powder and crystalline tetracycline. Venous blood was drawn from a healthy male of blood type O, Rh-positive and previously known to have a normal karyotype. A modified version of the Moorhead technique for leucocyte culture was adapted for use with smaller amounts of blood, and the blood sample was divided into six parts of 2 ml. each. Phytohemagglutinin (Difco, form M) was used for the separation of red cells, and the plasma obtained was added to the culture medium (TC 199) so as to give final antibiotic concentrations of 0, 50, 250, 500, 1,000 and 2,000  $\mu\text{g/ml}$ . The fixative used was glacial acetic acid and methanol (1:3). Slides were flamed over an alcohol lamp. The higher antibiotic concentrations used were well above those which have been found in the blood serum of individuals after the administration of antibiotics in therapeutic amounts<sup>1</sup>. Each antibiotic was tested twice at all six concentrations.

Fig. 1. — — — —, Penicillin; —, streptomycin; ·····, chloramphenicol; — · — ·, tetracycline

When possible, the number of chromosomes in 50 cells was counted as well as the number of mitoses per 1,000 leucocyte cells at each concentration. Any abnormalities, such as an atypical number of chromosomes per metaphase or alterations in chromosome morphology, were noted.

Analysis of the metaphases revealed few chromosomal aberrations in any of the cultures. With occasional exceptions, there were 46 chromosomes in each metaphase examined, and the number of chromosomal breaks and gaps was within normal limits of 2–5 per cent, as observed in control groups by Nichols *et al.*<sup>2</sup>. The occasional metaphases with 45 chromosomes were evidently products of broken cells. The findings mentioned here do not, of course, exclude chromosomal alteration at the molecular level. The chromosomes had a tendency to clump together in the highest concentration of streptomycin, chloramphenicol or tetracycline, and good spreading of the metaphases on the slide for examination was difficult to achieve. It was not possible, therefore, to count 50 metaphases at the 2,000-μg concentrations, or to determine whether or not many breaks or gaps were present.

The effects of a given antibiotic on the mitotic index varied according to its concentration, as shown in Fig. 1. The most striking effect is seen to be that of tetracycline, which inhibited mitoses completely at concentrations of more than 150 μg/ml. The tetracycline cultures were made at antibiotic concentrations of 0, 50, 100, 150, 200 and 250 μg/ml. of medium to bracket more accurately the toxic concentrations. This was done after the first series failed to produce mitoses at concentrations of more than 50 μg/ml. Although the graph indicates zero mitoses at the 200 μg/ml. level, a scanning of all the slides revealed two metaphases which were too clumped together for analysis. A small amount of precipitate was formed in the tetracycline cultures after a few hours in the incubator, a phenomenon also encountered by Hu *et al.*<sup>3</sup>. The amount of precipitate was negligible in the second series run with lower concentrations.

In the range of 500 μg/ml., streptomycin apparently stimulated mitoses. There were very slight increases in mitotic activity with lower concentrations of penicillin and chloramphenicol; but these peaks were not as convincing as in the case of streptomycin. Wilson has found that certain concentrations of penicillin had a slightly stimulatory effect on mitosis in root tips of the onion (*Allium cepa*)<sup>4</sup>.

The concentrations at which the four antibiotics tested were found to be inhibitory to mitosis in the leucocyte cultures of the present experiments were, for the most part, in agreement with those levels found to inhibit mitoses in human skin cultures<sup>5</sup>. The high concentrations of antibiotics used in the cultures are not known to be reached in blood serum when given in therapeutic amounts, except perhaps transiently at the site of

administration. Higher levels might also be found at sites of elimination, degradation or deposition. For example, 14.9 μg/ml. is one of the highest concentrations of tetracycline which has been reported for blood serum, whereas up to 320 μg/ml. of tetracycline has been measured in urine<sup>1</sup>.

Tetracycline is known to interfere with normal bone growth in chicks, rats and human infants<sup>6,7</sup>. It is also of interest that serum concentrations of penicillin, streptomycin, chloramphenicol and terramycin in the therapeutic range have been shown to traverse the placenta<sup>7</sup>. Some clinical investigations have suggested a relationship between antibiotic therapy of mothers and congenital abnormalities in their children<sup>8,9</sup>.

It would seem at least a possibility that the *in vitro* effects of these antibiotics on leucocyte mitosis as noted in the present investigation have some relevance to their effects in the intact, growing organism.

Samples of penicillin and streptomycin were kindly provided by E. R. Squibb and Sons; chloramphenicol by Parke, Davis and Co.; and tetracycline by Bristol Laboratories.

### Photochemical Oxidation and Reduction of Plastoquinone sensitized by Isolated Chlorophylls

SINCE the discovery of plastoquinone in chloroplasts by Crane<sup>1,2</sup>, many investigations have been reported on the role of the quinone in photosynthesis. Bishop<sup>3</sup> showed that the quinone participated in the photolysis of water. Krogmann<sup>4</sup> and Krogmann and Olivero<sup>5</sup> demonstrated the indispensability of the quinone as a co-factor for photophosphorylation. Crane *et al.*<sup>6</sup> and Redfearn and Friend<sup>7</sup> observed photo-induced reduction and dark reoxidation of the quinone in chloroplasts. The localization of plastoquinone in the electron transport system of photosynthesis was verified by Witt's school<sup>8,9</sup>. They indicated that the quinone acted as a primary electron acceptor from photochemically reduced chlorophyll *a*. Since all these investigations were carried out with chloroplasts, no evidence has been presented showing the direct interaction of plastoquinone with chlorophylls. Tollin and Green<sup>10</sup> observed electron paramagnetic resonance signals, showing the light-induced single electron transfer reactions between chlorophyll *a* and various kinds of quinones, but plastoquinone was not included among the quinones they used. In this communication, we present evidence indicating that plastoquinone can be

oxidized or reduced photochemically in the presence of chlorophyll *a* or *b*.

Chromatographically pure chlorophyll *a* and *b* were prepared according to the method of Perkins and Roberts<sup>11</sup>. Crystalline plastoquinone and its reduced form were prepared as described by Crane<sup>2</sup>. Photo-reduction of plastoquinone was carried out in a small Thunberg-type tube. An ethanolic solution contained 0.056  $\mu$ mole of chlorophyll *a*, 0.145  $\mu$ mole of plastoquinone and 50  $\mu$ moles of ascorbic acid in a total volume of 2 ml. The tube containing the above reaction mixture was evacuated for 5 min with a vacuum pump. After standing for a further 10 min in the dark, the mixture was illuminated for 15 min with a 500-W white incandescent tungsten lamp through a 10-cm water layer, which gave a light intensity of approximately 40,000 lux. The reaction was run at room temperature, about 20° C. After illumination, 0.5 ml. of 0.25 N HCl and 4 ml. of iso-octane were added. The mixture was transferred into a small glass-stoppered centrifuge tube. After shaking vigorously, the mixture was centrifuged at a low speed. The upper iso-octane layer contained plastoquinone, while ascorbic acid remained in an aqueous ethanolic layer. Then the absorption spectrum of the iso-octane layer was measured with the Hitachi recording spectrophotometer, type 'EPS-2'. Fig. 1*a* shows the spectrum of the illuminated sample (curve 1). After standing for 3 h in the dark, the spectrum of the same sample was measured (curve 2). Fig. 1*b* also shows the spectrum of the sample wrapped with aluminium foil to protect from light (curve 1), and that measured after reduction with sodium borohydride (curve 2).

These spectra indicate that plastoquinone could be photoreduced in the system described here (Fig. 1*a*, curve 1) and reoxidized slowly in the dark (Fig. 1*a*, curve 2), and that thermal or dark reduction of plastoquinone by ascorbic acid was negligible (Fig. 1*b*, curve 1).

The reaction velocity of the photoreduction was determined as follows; ethanolic solution containing 0.02  $\mu$ mole of chlorophyll *a*, 0.75  $\mu$ mole of plastoquinone and 250  $\mu$ moles of ascorbic acid in a total volume of 10 ml. was placed in a small 'lollipop' and bubbled throughout the experiment by a stream of nitrogen. Light from a 200-W projection lamp was passed through a red filter (which cut off the wave-lengths shorter than 600 m $\mu$ ) and a 10-cm water layer. The light intensity was approximately 7,000 lux. An aliquot (2 ml.) was taken from the mixture at various time intervals, and each aliquot was treated as described here. The photoreduction was found to be of second order and the initial velocity of the reaction was 12.3  $\mu$ moles plastoquinone photoreduced/min/mg chlorophyll *a*. On an equivalent electron basis, the rate was about ten times faster than that of the Hill reaction by isolated spinach chloroplasts, since 1.38–1.86  $\mu$ moles 2,6-dichlorophenol indophenol was found to be photoreduced/min/mg chlorophyll under the same experimental conditions.

On the other hand, the dye was reduced instantaneously with reduced plastoquinone. Therefore the Hill reaction using the dye as an oxidant may be drawn in the following scheme in which plastoquinone acts as a primary electron acceptor from chlorophyll *a*.

Fig. 1. Chlorophyll *a*-sensitized photoreduction of plastoquinone by ascorbic acid. *a*, Curve 1, spectrum measured immediately after illumination; curve 2, spectrum measured 3 h after illumination; *b*, curve 1, spectrum of non-illuminated sample; curve 2, spectrum measured after reduction with a few grains of borohydride

Table 1 shows that the presence of chlorophyll *a* or *b*, and ascorbic acid as an electron donor, was necessary for the photochemical reduction of plastoquinone, and that both chlorophyll *a* and *b* were almost equally effective.

Table 1. PHOTOREDUCTION OF PLASTOQUINONE: REQUIREMENTS OF A SENSITIZER AND AN ELECTRON DONOR\*

Sensitizer	Reductant	Oxidant	$\mu$ mole plastoquinone photoreduced per 15 min
Chlorophyll <i>a</i>	Ascorbic acid	Plastoquinone	0.145
Chlorophyll <i>b</i>	Ascorbic acid	Plastoquinone	0.145
—	Ascorbic acid	Plastoquinone	0.018
Chlorophyll <i>a</i>	—	Plastoquinone	0.027

\* A complete reaction mixture contained 0.056  $\mu$ mole of chlorophyll *a* or 0.002  $\mu$ mole of chlorophyll *b*, 50  $\mu$ moles of ascorbic acid and 0.145  $\mu$ mole of plastoquinone.

Auto-oxidation of reduced plastoquinone was also sensitized by chlorophyll *a* or *b*. The reaction was followed in 3 ml. quartz cell having a light path of 1.0 cm. Ethanolic solution containing either 0.056  $\mu$ mole of chlorophyll *a* or 0.062  $\mu$ mole of chlorophyll *b* and 0.054  $\mu$ mole of reduced plastoquinone in a total volume of 3 ml. was illuminated with a white incandescent lamp (40,000 lux). As a dark control, the cell was wrapped with aluminium foil. The spectrum taken after reaching a steady-state level showed the typical absorption peak of oxidized plastoquinone at 255 m $\mu$ . The time course of the oxidation is shown in Fig. 2. Here also the sensitizing activity of chlorophyll *a* and *b* was essentially the same.

Fig. 2. Time course of the photochemical oxidation of reduced plastoquinone sensitized by chlorophylls. Curve 1, with chlorophyll *b* as a sensitizer. Curve 2, with chlorophyll *a*. Curve 3, dark control with chlorophyll *a*. Arrow indicates time of turning on the light

### Chromatography of Soluble Macromolecular Components of HeLa Cells

ONLY limited success has been obtained in the electrophoretic analysis of soluble macromolecular components from HeLa human cancer cells or other cells grown *in vitro*. The separation is poor, and the fractions overlap; in the case of HeLa cells, the relatively best results have been obtained with starch gel<sup>1</sup>. Macromolecules can be efficiently fractionated on cellulose ion exchangers, and under strictly defined conditions their chromatographic properties may be as characteristic for them as electrophoretic mobility and behaviour in sedimentation. In the work recorded here, the chromatography on DEAE-cellulose columns of soluble components of HeLa cells has been studied. In view of the small amount of material available, micromethods have been applied, and both proteins and nucleic acids have been estimated sensitively by their absorption at 210 m $\mu$ . Amounts of the order of 1–3 mg protein could still be analysed.

HeLa cells were grown in bottles (40 cm<sup>2</sup> surface) containing 10 ml. of a salt-lactalbumin hydrolysate medium with 10 per cent human cord serum. Usually the material of 5–15 bottles, amounting to  $(50-150) \times 10^6$  cells, was used for an experiment. The cells were collected, washed, suspended in 1–2 ml. of 0.01 M phosphate buffer (pH 7.3–7.4) containing 0.003 M MgCl<sub>2</sub>, and treated in an all-glass Potter-Elvehjem homogenizer. Unbroken cells, nuclei and mitochondria were sedimented by centrifugation at 10,000*g* for 10 min. The supernatant was further fractionated into the microsomal and the 105,000*g* supernatant fraction in a Spinco preparative ultracentrifuge. The microsomal pellet suspended in 0.01 M phosphate buffer and the supernatant fraction were dialysed against the starting buffer before chromatography.

Elution was carried out with a series of phosphate buffers (KH<sub>2</sub>PO<sub>4</sub>-Na<sub>2</sub>HPO<sub>4</sub>) of constant pH (7.2) and increasing molarity from 0.01 up to 0.3 M. Two additional eluants were 0.3 M KH<sub>2</sub>PO<sub>4</sub> and 0.3 M KH<sub>2</sub>PO<sub>4</sub> + 1 M NaCl. The absorption was determined at 210 m $\mu$  against a blank of the corresponding buffer<sup>2</sup>. Occasional readings were taken also at 260 m $\mu$ . The content of nucleic acids is reflected by the 210/260 ratio. It was higher than 10 for the majority of fractions. It was, however, only 2–3 for the 0.3 M KH<sub>2</sub>PO<sub>4</sub> + 1 M NaCl fraction; clearly nucleic acid is present here.

The separation is efficient and well reproducible. The chromatographic profile obtained appears to be characteristic of soluble cell components and differs decidedly from that obtained with serum proteins. Soluble macromolecular components from other cells grown *in vitro* (human fibroblasts) as well as from freshly isolated spleen and liver cells give similar patterns. General features are

Fig. 1. Chromatogram of 105,000*g* supernatant after dialysis overnight against the starting buffer. 0.5 ml. of the solution with an absorbancy 150 at 210 m $\mu$  were placed on a 15 cm  $\times$  0.7 cm column loaded to a height of 10 cm; the flow rate was 5 min per fraction (2.2–2.4 ml. each).

the large amount of material eluted with buffers in the 0.1–0.3 M range, and the nucleic acid content of the last fraction.

Differential ultracentrifugation and subsequent analysis of the microsomes and the 105,000*g* supernatant showed that the components eluted in the 0.01–0.1 M range occur predominantly in the latter fraction (Fig. 1). Components emerging from the column at higher buffer molarity are present both in the microsomal and supernatant fraction (Figs. 1 and 2). This distribution probably reflects differences in chemical nature as well as in molecular size. Heterogeneity in molecular weight was confirmed by gel filtration on 'Sephadex G-200' of microsomes and supernatant<sup>3</sup>.

In the elution of serum proteins, at 0.08 M mainly albumins appear. In the case of HeLa, little material is present in this range. Similarly, only little protein with the electrophoretic mobility of albumins had been found in HeLa<sup>1</sup>. Fractions obtained at <0.08 M in HeLa probably correspond to components with the mobility of  $\alpha$ - and  $\beta$ -globulins<sup>1</sup>. One fraction is of special interest, namely, that eluted at 0.01 M and containing material not adsorbed

Fig. 2. Chromatogram of microsomal fraction. The pellet was suspended in 0.01 M phosphate buffer and dialysed overnight against this buffer. 0.5 ml. of the solution with an absorbancy 70 at 210 m $\mu$  were placed on the column and separated as described under Fig. 1.

on the ion exchanger. In the serum protein system, this fraction has been shown to consist of  $\gamma$ -globulins. An electrophoretic fraction with the mobility of  $\gamma$ -globulin has been demonstrated in HeLa proteins<sup>4</sup>, and at least part of the 0.01 M fraction appears to be identical with it.

In the presence of iron, HeLa cells produce ferritin<sup>5</sup>. We have grown HeLa with 10  $\mu$ g FeSO<sub>4</sub> and 0.3–1  $\mu$ c. <sup>59</sup>Fe per ml. The radio-iron was found in three peaks after chromatography of the homogenate, two of them emerging from the column with the 0.2 and 0.3 M phosphate buffers, and the third with 0.3 M KH<sub>2</sub>PO<sub>4</sub> + 1 M NaCl. Purified horse spleen ferritin<sup>6</sup> gave a chromatogram much like that of the component containing radio-iron from HeLa. Further evidence that the radioactivity is due to ferritin has been obtained by gel filtration on 'Sephadex G-200' (ref. 3). In paper electrophoresis, the mobility of the radioactive component of HeLa was identical with that of purified ferritin from horse spleen, but a little greater than that of ferritin from normal human liver. This is consistent with results from polyacrylamide gel electrophoresis<sup>7</sup>.

It appears, then, that DEAE-cellulose chromatography in conjunction with the measurement of ultra-violet absorption at 210 m $\mu$  and of radioactivity is an efficient method for the separation and identification of soluble macromolecular cell components.

### Identity of Cow $\beta$ -Lactoglobulin 'B' and Buffalo $\beta$ -Lactoglobulin

SINCE the demonstration by Aschaffenburg and Drewry<sup>1,2</sup> that  $\beta$ -lactoglobulins of cow's milk occur in two different forms, 'A' and 'B', many attempts have been made to find the differences in the primary structure of these two protein types. The differences between the two genetic species have been shown<sup>3,4</sup> to lie in the contents of four amino-acids, namely, aspartic acid, valine, glycine and alanine,  $\beta$ -lactoglobulin A having one more residue each of aspartic acid and valine and one less residue each of glycine and alanine than  $\beta$ -lactoglobulin B per half molecule. Likewise, chymotryptic peptide pattern analyses of sulphonated  $\beta$ -lactoglobulins A and B have indicated similarity of peptide pattern except for a single pair in which one aspartic acid residue in 'A' is replaced by one glycine residue in the corresponding 'B' peptide<sup>5</sup>. Information regarding the buffalo  $\beta$ -lactoglobulin, on the other hand, is scanty. It has been reported<sup>6,7</sup> that cow  $\beta$ -lactoglobulin B and buffalo  $\beta$ -lactoglobulin have approximately the same molecular weight and are practically indistinguishable in crystal form, electrophoresis, sedimentation and ultra-violet absorption.

The present report deals with the structural characterization of cow  $\beta$ -lactoglobulin B and buffalo  $\beta$ -lactoglobulin by means of amino-acid composition and peptide pattern analysis.

Table 1. AMINO-ACID COMPOSITION OF COW  $\beta$ -LACTOGLOBULIN B AND BUFFALO  $\beta$ -LACTOGLOBULIN

Amino-acid	Ratio amino-acid to protein (g/100 g):	
	In cow $\beta$ -lactoglobulin B	In buffalo $\beta$ -lactoglobulin
Aspartic acid	11.02 (15)	10.73 (15)
Threonine	5.25 (8)	5.06 (8)
Serine	3.89 (7)	3.78 (7)
Glutamic acid	19.95 (25)	19.79 (25)
Proline	5.27 (8)	5.20 (8)
Glycine	1.55 (4)	1.60 (4)
Alanine	7.23 (15)	7.23 (15)
Valine	6.00 (9)	5.70 (9)
Methionine	3.09 (4)	2.02 (4)
Isoleucine	7.22 (10)	7.43 (10)
Leucine	15.58 (22)	15.86 (22)
Tyrosine	3.75 (4)	4.24 (4)
Phenyl alanine	3.60 (4)	3.42 (4)
Lysine	11.79 (15)	12.27 (15)
Histidine	1.44 (2)	1.61 (2)
Arginine	2.66 (3)	2.66 (3)
Tryptophan	2.00 (2)	2.11 (2)

The values represent averages of three determinations. Figures in parentheses represent nearest integers of the number of residues per half mole of protein of molecular weight 18,300. Tryptophan was determined on separate samples by ultra-violet spectroscopy (ref. 13).

Non-casein protein fractions were prepared by the method of Aschaffenburg<sup>2</sup>. Paper electrophoresis for the survey of whey proteins was run at 110–150 V on Whatman No. 1 paper for 15 h using barbitone-HCl buffer, pH 8.6 ( $I = 0.05$ ). Suitable samples of cow and buffalo  $\beta$ -lactoglobulins were crystallized according to the method of Larson *et al.*<sup>8</sup>, and were recrystallized four times before use. The three  $\beta$ -lactoglobulins were subjected to column chromatography on DEAE cellulose (0.65 m.equiv./g; Bio-Rad Lab., U.S.A.) according to the method of Piez *et al.*<sup>4</sup> with certain modifications. The elution of  $\beta$ -lactoglobulins was observed to occur between 0.04 M and 0.08 M NaCl in 0.05 M phosphate buffer, pH 5.8 (column 10 cm.  $\times$  0.9 cm; speed 30–40 ml./h). Appropriate fractions were dialysed and freeze-dried. The amino-acid composition was determined according to the method of Moore and Stein as adapted by Van der Helm<sup>9</sup>. Sulphonated derivatives were prepared by the method of Weil *et al.*<sup>10</sup>. Tryptic digests and 'fingerprints' of the native and *S*-sulphonated derivatives were prepared in the usual manner<sup>11</sup> with pyridine-butanolic acetic acid-water as the chromatographic solvent<sup>12</sup>.

A survey of the occurrence of cow  $\beta$ -lactoglobulins in the 'Gir' breed indicated that there is a more or less equal content of  $\beta$ -AB and  $\beta$ -B types, while  $\beta$ -A was not detected in any of 65 samples of milk examined. No polymorphism, however, was observed in the  $\beta$ -lactoglobulins in 20 milk samples each from 'Jaffarabadi' and 'Surti' breeds of buffaloes, which showed only one protein type. The evaluation by electrophoretic and chromatographic procedures indicated that cow  $\beta$ -lactoglobulin B was identical in its behaviour to buffalo  $\beta$ -lactoglobulin. The amino-acid composition of cow  $\beta$ -lactoglobulin B was also found to be similar to that of buffalo  $\beta$ -lactoglobulin (Table 1). The 'fingerprints' of the tryptic peptides of these two protein types were also similar (Fig. 1). No difference was found between cow  $\beta$ -B obtained from  $\beta$ -B

Fig. 1. Tracings of the 'fingerprints' of tryptic digests of cow  $\beta$ -lactoglobulin B and buffalo  $\beta$ -lactoglobulin. Electrophoretic buffer: Mcll's buffer pH 6.4. Chromatographic solvent: butanol-pyridine-acetic acid-water (30:20:8:24). Major peptide spots are marked boldly.

homozygotes and that isolated from cow  $\beta$ -AB through DEAE cellulose columns. These results suggest that cow  $\beta$ -B and buffalo  $\beta$ -lactoglobulin may be identical. Differences, if any, must be very small, involving uncharged groups.

This work was supported by a grant from the University of Poona. We thank the Panjrapole Dairy for samples of milk.

### Inhibition of Plasma Monoamine Oxidase by Cysteamine

CYSTEAMINE has been shown to cause a transient inhibition of diamine oxidase<sup>1</sup>, which was explained by its coupling with pyridoxal phosphate in a thiazolidine ring. Even when linked to pyridoxal phosphate thiols may undergo oxidation to the corresponding disulphides<sup>2,3</sup> in the case of cysteamine the non-enzymatic oxidation to cystamine liberates pyridoxal phosphate, and the diamine oxidase activity is restored. Because the enzyme oxidizes cystamine<sup>4</sup>, we have an interesting example of an inhibitor which is changed into a substrate during the reaction.

To test the suggestion that cysteamine acts as inhibitor by binding pyridoxal phosphate, we have examined its activity towards another pyridoxal dependent enzyme, plasma monoamine oxidase. This was obtained from beef plasma according to Yamada and Yasunobu<sup>5</sup>. The action of cysteamine on the oxidation of spermine or spermidine was examined with enzyme preparations purified up to the steps 3 and 4 of the above authors, with similar results. The enzymatic activity was determined by following the oxygen uptake in the Warburg apparatus.

Fig. 1 shows that in the presence of cysteamine the oxidation of spermidine is inhibited until all the cysteamine has been non-enzymically oxidized to the corresponding disulphide. This is clearly indicated by the biphasic behaviour of the curves of the oxygen uptake (Fig. 1, curves 3 and 4). After the oxygen consumption has reached the theoretical value for oxidation of the thiol to the disulphide, the enzyme starts to oxidize its own substrate. The complete oxidation of cysteamine at this point has been checked by the nitroprusside test. The non-enzymatic character of the cysteamine oxidation was demonstrated by incubation with a boiled enzyme (Fig. 1, curve 7). The inhibitory effect of cysteamine has also been obtained using spermine as substrate for the enzyme. The transient inhibition of monoamine oxidase by cysteamine, which is very similar to the inhibition already demonstrated for diamine oxidase, also supports the suggestion that this particular activity of cysteamine involves pyridoxal phosphate. In this respect cysteamine

Fig. 1. 2 mg of beef plasma monoamine oxidase purified up to the step 4 of ref. 5 were incubated in 0.1 M phosphate buffer pH 7, with the following compounds: curve 1, spermidine 10  $\mu$ moles; curve 2, spermidine 20  $\mu$ moles; curve 3, spermidine 10  $\mu$ moles + cysteamine 10  $\mu$ moles; curve 4, spermidine 20  $\mu$ moles + cysteamine 10  $\mu$ moles; curve 5, spermidine 10  $\mu$ moles + cysteamine 10  $\mu$ moles; curve 6, cysteamine 10  $\mu$ moles. Temp.: 38°. Final volume, 3 ml. Gas phase: air. 2 mg of boiled enzyme were incubated in the same conditions with 10  $\mu$ moles of cysteamine (curve 7).

shows a noticeable specificity: another thiol tested, cysteine, which is unable to affect diamine oxidase<sup>1</sup>, is also ineffective on monoamine oxidase (Fig. 1, curve 5).

In the presence of cysteamine alone, an oxygen uptake greater than the theoretical amount for oxidation to the disulphide (Fig. 1, curve 6) indicates that cystamine is oxidized by the enzyme. Preliminary experiments in fact have shown that the purified plasma monoamine oxidase oxidizes cystamine, in agreement with results obtained with ox plasma by Bergeret and Blaschko<sup>6</sup>.

### Conversion of Cyano- and Hydroxo-cobalamin *in vivo* into Co-enzyme Form of Vitamin B<sub>12</sub> in the Rat

SINCE 5,6-dimethylbenzimidazolyl cobamide co-enzyme (DBCC) was shown to be one of the active forms of vitamin B<sub>12</sub> by Barker *et al.* in 1959 (ref. 1), its biochemical co-enzymatic activity (conversion of glutamate to methyl aspartate, methyl malonyl-CoA to succinyl-CoA, and 1,2-diols to aldehydes) and its physiological metabolism (tissue distribution, excretion and absorption) have been investigated<sup>2-8</sup>. It is now believed that vitamin B<sub>12</sub> exists as a co-enzyme form in the liver, and takes part in the transformation of methyl malonyl-CoA to succinyl-CoA (ref. 9). On the other hand, enzymatic synthesis of DBCC from B<sub>12</sub> derivatives has been confirmed by several workers at the bacterial enzymatic level. It has been reported that the liver and kidney homogenate of rat could convert cyanocobalamin (CN-B<sub>12</sub>) to co-enzyme B<sub>12</sub> *in vitro*<sup>10</sup>. But the only report indicating that CN-B<sub>12</sub> or hydroxocobalamin (OH-B<sub>12</sub>) can be converted to co-enzyme form *in vivo*, on the quantitative base, is Fenrych's short communication reporting the conversion of CN-B<sub>12</sub> into the

Table 1. CONVERSION OF CN-B<sub>12</sub> AND OH-B<sub>12</sub> TO DBCC IN RAT LIVER 3, 12 AND 24 h AFTER ADMINISTRATION

	Administration of			
	CN-B <sub>12</sub>		OH-B <sub>12</sub>	
	Alone	With H.I.F.	Alone	With H.I.F.

co-enzyme form in rabbit<sup>11</sup>. Our preliminary report concerning this conversion, which was obtained by <sup>57</sup>Co-labelling of the DBCC fraction in rat liver following the intravenous administration of <sup>57</sup>Co-labelled CN-B<sub>12</sub> and <sup>57</sup>Co-labelled OH-B<sub>12</sub> in rat, will be described here.

Male albino rats of Wistar strain weighing 150–200 g received, by intravenous injection, 100 μg of <sup>57</sup>Co-labelled CN-B<sub>12</sub> or <sup>57</sup>Co-OH-B<sub>12</sub> with or without 5 mg of hog intrinsic factor (H.I.F.) (Bifactor) and killed 3, 12 and 24 h afterwards. The rat liver was removed, homogenized in acetone and filtered, and then the residue was dried. The acetone powder was extracted with ethanol and the filtrate was again dried at 40°C *in vacuo* and then dissolved in water, according to Barker's method<sup>1</sup>. An aliquot of this solution was placed on 10 × 1 cm P-cellulose column (Serva, Entwicklungslabor, Heidelberg) buffered with 0.1 N acetate buffer of pH 3.5. CN-B<sub>12</sub> was eluted with distilled water, OH-B<sub>12</sub> with 0.05 M CH<sub>3</sub>COOH at pH 3 and DBCC with 0.1 M CH<sub>3</sub>COONH<sub>4</sub> of pH 6.9, respectively. Identification of B<sub>12</sub> derivatives was made by absorption spectra with a Beckman-type spectrophotometer as well as by isotopic counting of a paper-strip-electrophoretogram which was done with pH 2.7 acetate at 16 V/cm for 3.5 h. The chromatographic separation and identification of CN-B<sub>12</sub>, OH-B<sub>12</sub> and DBCC was based on the method by Kato *et al.*<sup>12</sup> and will be reported elsewhere in detail. The counting of the DBCC fraction was done with a well-type scintillation counter with a Type SP-1 spectrometer (Shimadzu Co., Ltd., Japan), and the conversion rates and amounts were calculated.

The results obtained in normal rats are shown in Table 1. The amounts of DBCC converted from the administered CN-B<sub>12</sub> 3 h after administration, with and without H.I.F., were 4.04 and 0.63 μg, respectively. The conversion rates increased with time, and the converted DBCC amounted to 0.96 and 2.05 μg, 12 and 24 h after the administration without H.I.F., and 2.04 and 3.04 μg when given with H.I.F. It is interesting that the intravenous co-administration of H.I.F. enhanced not only the hepatic uptake but also amounts of DBCC converted from CN-B<sub>12</sub>, although the conversion rates were rather low, as compared to those without H.I.F. OH-B<sub>12</sub>, which perhaps occupies a more important position in B<sub>12</sub> metabolism than CN-B<sub>12</sub> (refs. 13 and 14), showed higher conversion to DBCC as compared to CN-B<sub>12</sub>. The amount of DBCC converted from <sup>57</sup>Co-OH-B<sub>12</sub> was approximately three times that from <sup>57</sup>Co-CN-B<sub>12</sub>, 3, 12 and 24 h after the administration without H.I.F. On the other hand, although a little more

DBCC was converted from OH-B<sub>12</sub> than from CN-B<sub>12</sub> 3 h after the administration when given with H.I.F., almost three times as much was obtained after 12 and 24 h.

The conversion of CN-B<sub>12</sub> or OH-B<sub>12</sub> to DBCC in rat liver pre-treated with 10 per cent carbon tetrachloride is shown in Table 2. One hundred μg of <sup>57</sup>Co CN-B<sub>12</sub> or <sup>57</sup>Co-OH-B<sub>12</sub>, with or without H.I.F., was intravenously injected 6 or 12 h after the intraperitoneal administration of CCl<sub>4</sub>, and the liver was removed 3 h after B<sub>12</sub> injection. As the conversion is thought to occur in the liver, and a significant decrease of DBCC content was found in CCl<sub>4</sub>-injured liver<sup>15</sup>, it is reasonable to presume that the conversion is decreased in the injured liver. It was found that the hepatic uptake of CN-B<sub>12</sub> and OH-B<sub>12</sub> was decreased 6 h after CCl<sub>4</sub> administration and again increased after 12 h. But conversion to DBCC did not recover even after 12 h; and more OH-B<sub>12</sub> than CN-B<sub>12</sub> was converted to DBCC.

It can be concluded that CN-B<sub>12</sub> or OH-B<sub>12</sub> are converted into the co-enzyme form of B<sub>12</sub> in the normal rat liver. Though 100 μg of <sup>57</sup>Co-CN-B<sub>12</sub> or <sup>57</sup>Co OH-B<sub>12</sub> is thought to be beyond the physiological dose, this dose was used to obtain enough counts for measurement. These results also suggest that the disturbance of CN-B<sub>12</sub> utilization, generally used in the clinical field, could occur in some conditions with liver injury and, furthermore, therapeutic application of OH-B<sub>12</sub> has an advantage over that of CN-B<sub>12</sub> in patients with liver diseases<sup>16</sup>, not only because of its reported retention for a long time in the blood stream but also because of its easy convertibility to co-enzyme form. On the other hand, the results of CCl<sub>4</sub> injury indicated a more significant disturbance of the conversion of CN-B<sub>12</sub> than of OH-B<sub>12</sub> to DBCC. This appears to suggest that CN-B<sub>12</sub> will be transformed to DBCC through OH-B<sub>12</sub> and CCl<sub>4</sub> injury primarily disturbs the pathway from CN-B<sub>12</sub> to OH-B<sub>12</sub>. Work on the effect of ATP or FAD administration on this conversion reaction *in vivo*, and possible increase of conversion in the B<sub>12</sub>-deficient rat, is now in progress.

This work was supported in part by a grant-in-aid from the Rockefeller Foundation. <sup>57</sup>Co-CN-B<sub>12</sub> and <sup>57</sup>Co OH-B<sub>12</sub> were supplied by Dr. Kalman C. Mezey, Merck Sharp and Dohme, Rahway, New Jersey, U.S.A., and DBCC by Dr. David Perlman, Squibb Institute for Medical Research, New Brunswick, New Jersey, U.S.A.

## PHYSIOLOGY

Circulatory and Metabolic Processes in Adipose Tissue *in vivo*

To permit the study *in vivo* of circulatory and metabolic processes in adipose tissue, a part of the dog's subcutaneous tissue was prepared with intact circulation and innervation. The preparation was found to be suitable for quantitative investigations on the nervous control of the blood flow and of the release of free fatty acids. We considered it to be of general interest to describe the method and some of its applications.

The experiments were performed on female mongrel dogs (weight 10–15 kg) anaesthetized with sodium pentobarbital (30 mg/kg with supplement as necessary). The animals were fasted for about 24 h. The subcutaneous adipose tissue in the lower abdominal region was exposed by a midline incision from the pubis to the level of the pubic mammary glands. The left or right part of the subcutaneous adipose tissue was then isolated from the overlying skin and the underlying abdominal muscles by cautery and blunt dissection. The adipose tissue was tied both caudally and cranially with ligatures. The cranial ligatures isolated the adipose tissue from the mammary glands. Great care was taken to leave the nerves and blood vessels supplying the adipose tissue undamaged during the preparation. One or sometimes two nerves (n. iliohypogastricus, n. ilioinguinalis) accompanied the artery and the vein (a. et v. epigastrica superficialis) from the external hiatus of the inguinal canal to the adipose tissue.

When the foregoing nerves and vessels had been prepared, all other vascular connexions between the adipose tissue preparation and the rest of the dog were ligated. The skin was replaced to maintain warmth and moistness. The adipose tissue prepared in this way weighed between 23 and 97 g (mean 44 g,  $n = 17$ ). In 5 dogs, blood flow was measured by cannulating the vein and directing the blood through a drop chamber filled with silicone oil. Heparin was administered (intravenously) to prevent clotting. In 12 dogs, the tissue was perfused at a constant flow rate with defibrinated blood from the same dog via the superficial epigastric artery, by means of a technique described by Renkin and Rosell<sup>2</sup>. Heparin was not used when the release of free fatty acids was examined, as it is known to release the clearing factor lipase. The ipsilateral sympathetic chain was isolated via the anterior approach and transected. The peripheral ends of the cut sympathetic chain or the cut nerves to the adipose tissue were stimulated with a Grass *S 4D* stimulator. For the study of release of free fatty acids, arterial samples were taken from the blood reservoir in the perfusion apparatus. Venous blood samples were collected during 1- to 5-min periods. Free fatty acids were determined in each sample according to Dole<sup>3</sup> as modified by Trout, Estes and Friedberg<sup>4</sup>. The net uptake or release was calculated as the arteriovenous free fatty acid difference times plasma flow.

Acute denervation did not change flow of blood significantly. Blood flow in the acutely denervated preparation was found to vary between 3.4 and 9.3 ml./min.100 g tissue (mean value = 6.7 ml./min.100 g,  $n = 5$ ). A pronounced vasoconstriction occurred following stimulation of the sympathetic chain (2–5 V) at the level of  $L_1$ – $L_3$  or stimulation of the appropriate peripheral nerves. When stimulation had ceased the vasoconstriction was sometimes followed by a vasodilatation for several minutes. The vasoconstriction was blocked by dihydroergotamine, indicating that it was due to the stimulation of adrenergic vasoconstrictor nerves. Stimulation following the administration of dihydroergotamine induced a vasodilatation. This could not be blocked by atropine, which indicates that it was not due to the stimulation of cholinergic vasodilator nerves similar to those innervating

skeletal muscle vessels<sup>5</sup>. No further attempts have so far been made to analyse the mechanism for this vasodilatation.

In another series of experiments, the adipose tissue was perfused with defibrinated blood at a constant level of flow and the net release of free fatty acids determined. The level of flow was set at a value giving approximately the same perfusion pressure as the prevailing arterial blood pressure. Such an experiment is illustrated in Fig. 1. The perfusion pressure was about 100 mm Hg at a constant blood flow of 8.1 ml./min.100 g. Before the nerves to the preparation were stimulated there was a small net uptake of free fatty acids. Electrical stimulation of the appropriate nerves (3 i.p.s.) resulted in an immediate and pronounced increase in perfusion pressure. The net outflow of free fatty acids did not change appreciably during the 10-min stimulation period. When stimulation was discontinued the perfusion pressure returned towards resting level. A net release of free fatty acids occurred, with a maximum of about 0.9  $\mu$ equiv./min.100 g adipose tissue. By about 15 min after stimulation had stopped the net release of free fatty acids was back to prestimulation level and there followed a period of net uptake. Similar results were obtained by stimulating the sympathetic chain at the level of  $L_1$ – $L_3$ .

Fig. 1. Perfused subcutaneous adipose tissue from dog. Changes in perfusion pressure and in the net release of free fatty acid (FFA) with electrical stimulation of the nervous supply (5 V, 10 msec, 3 i.p.s.)

Spitzer and Hohenleitner<sup>6</sup> determined the change in plasma free fatty acids on passage through the abdominal subcutaneous tissue in dogs. Their technique, however, did not permit any quantitative determinations of the release of free fatty acids, mainly due to a lack of information on blood flow in the tissue. Our results indicate that there is an appreciable flow of blood in the subcutaneous adipose tissue in dog under resting conditions. A mean value of about 7 ml./min.100 g is in the upper range for resting blood flow in, for example, the skeletal muscles<sup>7</sup>. Moreover, it is directly shown that electrical stimulation of the nervous supply to subcutaneous adipose tissue stimulates the release of free fatty acids, which is in accordance with the results obtained by Correll<sup>8</sup> from *in vitro* experiments. Furthermore, it is demonstrated that there is a pronounced net release of free fatty acids during nerve stimulation at frequencies considered to be within the physiological range (3 i.p.s.).

## Free and Bound Noradrenaline in the Rabbit Heart

SUB-CELLULAR storage particles containing noradrenaline (NA) have been demonstrated in noradrenergic nerves and in organs supplied with such nerves<sup>1,2</sup>. The nerve vesicles, which have a diameter of 0.03–0.1  $\mu$  (ref. 3), have been subjected to a number of investigations regarding stability in various media, release and uptake of NA and other amines, and action of drugs<sup>4,5</sup>.

The NA in the vesicles represents on an average  $28 \pm 3$  (S.D.) per cent of the total NA present in the press juice obtained from the nerves<sup>4</sup>. Higher proportions were obtained with the same technique applied to the suprarenal medulla, chromaffin cell tumours, and organs containing chromaffin cells. These results indicate that the major part of the noradrenaline in the nerve axons is free or loosely bound.

The NA-containing particles in the terminal portions of the adrenergic nerves, previously demonstrated in homogenates of organs<sup>1,6</sup>, show many properties in common with the nerve vesicles<sup>7,8</sup>.

Electron microscopic pictures<sup>9</sup> suggest that the proportion of vesicle-bound NA is considerably higher in the nerve terminals than in the pre-terminal axons. In the work recorded here NA was determined in the high-speed sediment (vesicle-bound) and in the soluble fractions of the homogenized rabbit heart.

Rabbits of both sexes, weighing 2–3 kg. were killed by air injection and the hearts immediately removed, washed in ice-cold phosphate buffer, blotted dry, and homogenized in 10 ml. buffer per g organ in an Ultra Turrax apparatus. The homogenate was subjected to differential centrifugation in order to separate the particulate fraction containing NA from the coarse fraction and the soluble NA. Previous experience from separation of the different fractions in press juice of bovine splenic nerves has shown that centrifugation at 9,000g for 10 min yielded a relatively pure particle suspension as shown by electron microscopic pictures<sup>3</sup>.

The supernatant after treatment of the rabbit heart homogenate in this way was later centrifuged at 100,000g for 45 min. The sediment contained a high proportion of vesicles of the same type as found in the nerve (Fig. 1).

The amounts of NA/g of rabbit heart and the proportion of NA in the different fractions are given in Table 1. All fractions were extracted with trichloroacetic acid and adsorbed on alumina. NA was determined fluorimetrically and the values are given as the base (uncorrected).

If the NA in the coarse fraction, representing mostly incompletely homogenized tissue, is subtracted from the total amount, the proportion of particle-bound NA to the sum of the bound and free NA was  $52 \pm 2.4$  per cent.

Fig. 1. Suspension of high-speed sediment from homogenate of rabbit heart. Negative staining with phosphotungstate. Inserted mark 0.1  $\mu$  ( $\times c. 36,000$ ).

Since the recovery of added NA to the homogenate was about 80 per cent, it was assumed that the loss by enzymatic breakdown was negligible.

The present results thus indicate that the proportion of vesicle-bound NA relative to the sum of the free and vesicle-bound NA is significantly higher than that in bovine splenic nerves, the difference being  $24 \pm 2.7$  per cent ( $P < 0.001$ ).

The relative as well as the absolute values obtained for the vesicle-bound NA in the rabbit heart may well be too low, since a portion of the vesicles will probably sediment with the coarse fraction. Moreover, it appears likely that the proportion of vesicle-bound NA is still higher in the varicosities proper which have been shown by histochemical<sup>10</sup> and electron microscopic technique<sup>9</sup> to have a high concentration of NA and vesicles.

Hertting and Hess<sup>11</sup> have reported that the specific activity of the NA in guinea-pig heart, after previous injection of tritiated NA in animals treated with reserpine, is unchanged at different degrees of depletion, suggesting that the intra- and extra-granular NA are in equilibrium. This has been shown with direct measurements for the rabbit heart in our laboratory<sup>5</sup>. In a series of experiments

Table 1. NA IN FRACTIONS OF HOMOGENIZED RABBIT HEART (Mean  $\pm$  S.E.M.)

	NA ( $\mu$ g/g)	% of total NA	% of sum of vesicle bound and soluble
Vesicle bound (high-speed sediment)	$0.66 \pm 0.091$	$39 \pm 1.5$	$52 \pm 2.4$
Soluble fraction	$0.66 \pm 0.053$	$36 \pm 1.7$	$48 \pm 2.4$
Coarse fraction (sediment from 9,000g)	$0.43 \pm 0.058$	$25 \pm 0.65$	—
Total	$1.7 \pm 0.18$	—	—

Table 2. RELATIONSHIPS BETWEEN TOTAL NA AND NA IN HIGH-SPEED SEDIMENT (VESICLE BOUND) AND IN THE SOLUBLE FRACTION OF HOMOGENIZED RABBIT HEART

	Decaborane treated				Controls $M \pm S.E.M.$
Total NA ( $\mu$ g/g)	0.21	0.60	0.71	0.82	$1.7 \pm 0.18$
Vesicle bound in % of total NA	33	36	35	34	$39 \pm 1.5$
Vesicle bound in % of soluble NA	80	105	86	93	$109 \pm 10.4$
Vesicle bound in % of sum of vesicle bound and soluble NA	45	51	46	43	$52 \pm 2.4$

on the rabbit heart partially depleted with decaborane we have also observed that the proportion of vesicle-bound NA in relation to the sum of vesicle-bound and soluble NA is approximately the same, independently of the total amount of NA (Table 2). If the vesicle-bound and the soluble NA are in dynamic equilibrium, as suggested by our experiments and by those of Michaelson *et al.*<sup>12</sup>, the concentration of the free NA might still be the same in the axons and in the terminal parts under normal conditions although the relative amounts of vesicle-bound and free NA are different.

The results recorded here show that the proportion of vesicle-bound NA in the terminal parts of the axons is considerably higher than that in the pre-terminal parts and that the proportions of NA in the high-speed sediment and in the soluble fractions of the homogenized rabbit heart are approximately constant and independent of the total amount of NA in the organ, suggesting a state of equilibrium between these fractions.

We thank Dr. K. C. Back, Wright Patterson Air Force Base, Ohio, for a generous supply of decaborane, and Mrs. A.-C. Bergström for her skilful assistance.

### Chemical Control of Sensory Ganglia during a Critical Period of Development

Two populations of cells appear during differentiation of sensory ganglia in the chick embryo. These have been designated as ventro-lateral (V-L) and median-dorsal (M-D)<sup>1-3</sup>. Changing the field of innervation, by either implantation or extirpation of limb buds, produces morphologic alterations solely in the V-L cells. The nerve growth-promoting protein (NGF), described and partially characterized by Levi-Montalcini and Cohen<sup>4-6</sup>, produces hyperplasia and hypertrophy of embryonic M-D sensory cells as well as sympathetic nerve cells. Although the growth-promoting effects of NGF on sympathetic cells persist into adulthood in various species, its stimulatory effect on sensory cells is restricted to the embryonic period of development<sup>5</sup>. It was the purpose of this investigation to delineate further the critical period during development when sensory ganglia exhibit a morphological response to purified NGF and to explore some of the mechanisms controlling the reactive sequence.

Fig. 1. Response of sensory ganglia of various ages to test concentrations of NGF (16-20 h incubation): (A), 6 day; (B), 7 day; (C), 13 day; (D) 14 day

NGF was purified from adult male mouse salivary glands according to a modification of the method of Cohen<sup>6,7</sup>. Anti-serum was prepared by serial injections of purified NGF with Freund's complete adjuvant into rabbits. A single band of precipitation is demonstrable following agar diffusion and immunoelectrophoresis when purified NGF is reacted against its anti-serum.

Sensory ganglia were removed from chick embryos on the fifth through the 14th day of incubation. *In vitro* demonstration of the growth-promoting effects of NGF was performed by a modification of the method of Levi-Montalcini<sup>8</sup>. The amount of NGF required to produce a 3+ response (arbitrary 1 to 4+ scale) in sensory ganglia from embryos incubated 9-10 days (approximately 0.02 to 0.08 µg/c.c.) was used when culturing ganglia from all embryos. The response to NGF was evaluated in terms of the characteristic appearance of a halo of fibres within 24 h. Ganglia grown *in vitro* prior to bioassay were cultured in depression slides, in a liquid medium of similar composition to that used for bioassay but omitting embryo extract.

Chick sensory ganglia react to NGF only from the seventh through the 13th day of incubation. Before 7 and after 13 days, they exhibit no visible growth when exposed to the nerve growth-promoting factor. Fig. 1 compares the reaction of 6-, 7-, 13- and 14-day ganglia. All these changes in response occur abruptly, since there is no demonstrable growth in 6- and 14-day ganglia even if tested with 100 times the concentration of NGF.

Although both 5- and 6-day ganglia are unresponsive, they exhibit a marked difference in their ability to develop this response in tissue culture. Ganglia removed at six days' incubation and grown for 24 h *in vitro* gain the ability to demonstrate fibre outgrowth when afterwards incubated with NGF. Those removed at five days and cultured for one or two days before testing remain unreactive (Table 1).

The abrupt loss of the capacity to exhibit fibre outgrowth in response to NGF, occurring between the 13th and 14th day of incubation, only occurs *in vivo*. Removal of sensory ganglia at 12 days, followed by two days in tissue culture, results in ganglia still able to respond. If 14-day ganglia, however, are grown for two days *in vitro*, they are still refractory to the effects of NGF.

If small amounts of NGF are added to ganglia from 5-day embryos in tissue culture, they remain unreactive when afterwards assayed with standard amounts of NGF. However, when a similar experiment is conducted with 12-day ganglia, no response to NGF can be demon-

Table 1. RESPONSE OF SENSORY GANGLIA TO NGF, AS DETERMINED BY NERVE FIBRE OUTGROWTH 16-20 h AFTER BEING PLACED IN PLASMA CLOT CULTURE

Culture medium includes: 1 part Eagle's basal medium-chick embryo extract (5:1), 1 part rooster plasma, 1 part NGF in 0.9 per cent saline (0.02-0.08  $\mu\text{g}/\text{c.c.}$  incubation media). *In vitro* refers to tissue culture period prior to bioassay. NGF added to tissue culture in a concentration (0.002-0.004  $\mu\text{g}/\text{c.c.}$  media) too low to effect fibre outgrowth (NGF *in vitro*)

Age of ganglia (days)		No. of experiments *	NGF <i>in vitro</i>	Response
Total	<i>In vivo</i>			
5	5	0	3	Neg.
6	5	1	3	Neg.
6	5	1	2	Neg.
6	6	0	3	Neg.
7	5	2	2	Neg.

14	12	2	4	Pos.
14	12	2	3	Neg.

\* Each experiment involves observations on 6-14 ganglia.

strated after 2 days in tissue culture. This change is age specific, since 10-day ganglia, similarly cultured, continue to respond two days later.

These changes in the response of ganglia at different ages do not reflect permeability factors. For the demonstration of permeability of ganglia to NGF by the fluorescent antibody technique, ganglia were incubated in liquid culture for 24 h at 37°C, washed in 0.01 M phosphate buffer, pH 6.8, and afterwards incubated for 30 min with specific anti-serum or control rabbit serum. The ganglia were re-washed with buffer and stained with goat anti-rabbit  $\gamma$ -globulin which had been previously conjugated with fluorescein (Antibodies, Inc., Davis, California). After washing again in buffer, the ganglia were mounted on slides and examined for specific fluorescence<sup>9</sup>. Using the fluorescent antibody technique, nerve growth-promoting protein is bound to 6- and 14-day ganglia after incubation for 24 h, even though no fibre growth occurs (Fig. 2).

These results indicate that sensory ganglia from chick embryos undergo a sequence of differentiative phases. Between the fifth and sixth day, a change occurs wherein they develop a characteristic response to NGF on the seventh day whether left *in vivo* or cultured *in vitro*. At 13 days, another change occurs, when ganglia lose their capacity to respond to NGF, in the time-sequence examined, only if left *in vivo*. While NGF does not seem to effect the initial change, the loss of reactivity may be under control of the nerve growth factor.

The developmental sequence described in these investigations provides a model system for the correlation of

morphological and biochemical events during various phases of differentiation of sensory ganglia.

## PHARMACOLOGY

### A General Theory of the Genesis of Drug Dependence by Induction of Receptors\*

DRUG dependence can occur in organisms as far apart as bacteria<sup>1</sup> and man, and even in isolated preparations of cells<sup>2</sup> or muscle<sup>3</sup>. The theory proposed here is intended to explain the genesis in mammals of dependence on addictive drugs, such as morphine; but there seems no reason why it might not apply to drug dependence in other organisms or in isolated preparations and to tolerance towards non-addictive drugs. This explanation is based on the concept of Ehrlich<sup>4</sup> that a chemical substance acts on a living system through its molecules becoming attached to particular sites (receptors) on cells. It uses the following aspects of receptor theory, which are to be found in pharmacological literature in other connexions.

(1) *Silent receptors*. Several authors have proposed that a drug may be taken up on certain receptors without producing an observable response<sup>5</sup>. Such receptors have been called 'silent receptors', 'sites of loss' or 'dead spots'. Silent receptors are conceived as reducing drug activity by taking up molecules which would otherwise reach 'active', 'audible' or 'live' receptors.

(2) *Interaction with endogenous substances*. A drug may act by depriving cells of an endogenous substance which plays a natural part in their working. Drugs are believed to do this by occupying receptors for that substance or by lessening the amount of it produced or released. For example, at the nerve-muscle junction, *d*-tubocurarine is believed to paralyse by blocking access of the natural transmitter (acetylcholine) to the muscle end-plate, and botulinum toxin to paralyse by reducing the amount of acetylcholine released<sup>6</sup>. A drug may also act by the opposite mechanism of producing an excess of endogenous substance, either

Fig. 2. Immunofluorescence of ganglia when incubated with specific anti-serum or control rabbit serum and tested with goat anti-rabbit  $\gamma$ -globulin coupled with fluorescein. (A), 14-day ganglia plus specific anti-serum; (B), 14-day ganglia plus control rabbit serum; (C), 6-day ganglia plus specific anti-serum; (D), 6-day ganglia plus control rabbit serum

\* I outlined this theory at the Ciba Foundation Study Group on Hashish in London on October 21, 1964.

by releasing it from store or by inhibiting its destruction.

(3) *Induction of receptors.* Ehrlich<sup>4</sup> held that new receptors for an antigen are produced when specific antibodies are formed. Miledi<sup>7</sup> has used the term 'induction of receptors' to describe the increase of sensitivity to acetylcholine which develops on skeletal muscle fibres elsewhere than at the end-plate, after transection of a muscle fibre or motor nerve. If a living system is distorted by excess or deficiency of chemical substance, induction of receptors in the direction lessening that distortion is to be expected. Thus a foreign chemical would tend to induce silent receptors for itself, whereas deprivation of an endogenous substance would tend to induce active receptors for the lacking substance. For example, within one or two weeks of its administration, botulinum toxin induces receptors for acetylcholine over the whole surface of the muscle fibre<sup>6</sup>. Increase in the number of accessible active receptors to an endogenous substance is assumed to increase the ease with which that substance can excite a tissue. A converse concept, that excess of an endogenous substance reduces the number of its receptors and the ease with which it excites a tissue, has also been proposed<sup>6</sup>.

Concepts 1 and 3 provide a mechanism by which tolerance might develop. This would be expected if one dose of drug were to induce new silent receptors, which would in turn take up part of a second dose of drug without giving a pharmacological response. This explanation has the advantage that it does not require an increase in enzyme destroying the drug, as has often been suggested, but has seldom been found sufficient to explain the degree of tolerance reached. To explain the development of tolerance to one action of a drug but not another, or the presence of tolerance in tissue isolated from a treated animal, silent receptors might be supposed to develop alongside active receptors in cells responding to drug. In so far as tolerance arises from induction of silent receptors for drug, it need not be associated with dependence. Tolerance associated with dependence might be expected to develop by the mechanism proposed below for dependence.

Concepts 2 and 3 provide a mechanism by which tolerance, withdrawal effects and craving for drug might arise. If a drug were to lessen the amount available to nerve cells of an endogenous substance concerned with their activity, this deprivation might be expected to induce additional active receptors for the substance. Tolerance to drug would develop as these extra receptors became available. When the blockade of receptors was lifted by withdrawing the drug, the endogenous substance would reach both original and extra receptors and so elicit excessive responses—the withdrawal effects. If the substance concerned had only psychic actions, the withdrawal effects would be psychic; if it also affected bodily systems, physical withdrawal signs might be expected. If the drug were again given, receptors for the endogenous substance would again be deprived and withdrawal effects abate. Drug would therefore be craved to prevent such effects. If the drug were to produce excess, instead of deficiency, of an endogenous substance, this might be expected to reduce the number of active receptors for that substance. From this reduction, tolerance and dependence would arise by a converse mechanism of the above.

An attempt to work out how the foregoing mechanisms would operate in a particular instance may be made with morphine. Some part of tolerance to morphine may arise through its induction of silent receptors; but, inasmuch as tolerance to morphine is associated with dependence, both might be expected to develop together, through morphine changing the availability to receptors of some endogenous substance concerned with central nervous activity.

Several known substances may be considered as candidates for the role of endogenous substance involved in

morphine dependence. Among these, 5-hydroxytryptamine (5-HT) would seem one of the more suitable, for several reasons: (1) morphine antagonizes some of the actions of 5-HT (refs. 8–10); (2) 5-HT has been supposed to be concerned with normal mental activity<sup>11,12</sup>; (3) 5-HT is continuously produced in brain<sup>13</sup>; (4) the effects of raising the brain concentration of 5-HT in dogs<sup>14</sup> resemble in several characteristics those of withdrawing morphine from addicted animals of that species<sup>15</sup>.

If morphine blockades 5-HT receptors on nerve cells, this might be expected to induce extra 5-HT receptors. On withdrawing morphine, endogenous 5-HT would reach the larger number of active receptors now available, eliciting excessive pharmacological reactions, which are the withdrawal effects. This series of events would explain the genesis of withdrawal effects without the need to postulate changes in concentration of 5-HT in the brain during morphine treatment and withdrawal, which do not happen<sup>16,17</sup>.

Since morphine inhibits release of acetylcholine from guinea-pig intestine<sup>3,18</sup>, acetylcholine provides an alternative endogenous substance which might be concerned in morphine dependence. Induction of acetylcholine receptors on nerve cells after deprivation of this substance by morphine might well be comparable to induction of acetylcholine receptors on muscle by botulinum toxin.

After chronic treatment of dogs and rats with morphine, its withdrawal lowers the level of catecholamines in the brain<sup>17,19–21</sup>. This implies that catecholamines may be involved in morphine dependence, but it need not conflict with the general theory here presented.

To summarize, the proposed explanation of the development of tolerance to and dependence on drugs is based on the concept of receptors. It requires five assumptions: (1) that receptors may be of two types—active and silent; (2) that the number of receptors of either type for a substance can increase or decrease at the same rate as tolerance or dependence develops; (3) that a drug causing dependence acts by increasing or decreasing the amount of an endogenous substance available to receptors; (4) that when excess or deficiency of a chemical substance distorts a living system, the numbers of receptors of either type for that substance change in the direction lessening the distortion; (5) that the ease with which a substance excites a tissue depends on the number of accessible receptors for that substance.

### Effect of Segontin and Reserpine on Isolated Medullary Granules

In a previous paper<sup>1</sup> we have shown that tyramine releases catecholamines but not ATP from isolated medullary granules, and that the released catecholamines are almost quantitatively replaced by the uptake of equimolar amounts of tyramine. Segontin [N-(3'-phenylpropyl-(2')-1,1-diphenylpropyl-(3)-amine], a potent dilator of the coronaries, causes, *in vitro* as well as *in vivo*, a release of catecholamines from the medullary granules<sup>2</sup>. In order to determine whether segontin acts like tyramine by displacing catecholamines from their binding sites we investigated the release of catecholamines and ATP by segontin and its uptake into the chromaffin granules. For comparison, experiments with reserpine were undertaken, as it is known that this compound also releases catecholamines from medullary granules *in vivo* and *in vitro*<sup>3,4</sup>.

The chromaffin granules were prepared from suprarenal medulla of cattle as previously described<sup>5</sup> and suspended in sucrose-phosphate buffer pH 6.8. The samples (7 ml.) were incubated for 60 min at 37° C under shaking. The granules of the incubated samples as well as of the non-incubated controls were sedimented by centrifugation (15 min, 12,000g, in stainless steel tubes), washed once with 3 ml. sucrose-phosphate buffer and sedimented with 12,000g. The granules were then suspended in 5 ml. saline; 4 ml. of this suspension were extracted with 0.15 ml. concentrated perchloric acid and centrifuged. The catecholamines and ATP were determined in the supernatant, the former by the method of v. Euler and Hamberg<sup>6</sup>, the latter by the method of Strehler and Totter<sup>7</sup>. In order to measure the uptake of <sup>14</sup>C-segontin, 1 ml. of the granular suspension was dried at 60° C and the residue dissolved in 1 ml. hyamine hydroxide at 40° C. After cooling, 10 ml. scintillator (4 g PPO and 100 mg POPOP in 1,000 ml. toluene) were added and the radioactivity was determined in a Packard 314X liquid scintillation spectrometer. An internal standard (<sup>14</sup>C-toluene) was used to correct for quenching and efficiency of counting.

Table 1. UPTAKE OF SEGONTIN BY ISOLATED CHROMAFFIN GRANULES AND ITS EFFECT ON THE RELEASE OF CATECHOLAMINES (CA)

Segontin ( $\mu$ M/sample)	Segontin uptake ( $\mu$ M)	Release of catecholamines ( $\mu$ M)	CA release/ Seg. uptake
0.165	0.060	1.39	48
0.280	0.098	2.27	78
0.476	0.124	2.92	100

The samples contain in 7 ml.: 2 ml. granules from 140 mg medullary tissue, 0.1 ml. segontin, 0.4 ml. <sup>14</sup>C-segontin (9.6  $\mu$ M; specific activity 5  $\mu$ Ci/2.4  $\mu$ M) and 4.5 ml. sucrose-phosphate buffer, pH 6.8. Incubation: 60 min at 37° C.

During incubation of isolated chromaffin granules at 37° C, catecholamines and ATP are released spontaneously to the same degree<sup>1,8</sup>. The addition of either 0.3  $\mu$ M segontin or 1  $\mu$ M reserpine per sample (Fig. 1) proportionally increases the release of catecholamines and ATP so that the original molar ratio, amine/ATP of 4 : 1, remains unchanged. Table 1 shows that during incubation with <sup>14</sup>C-segontin the uptake of segontin, as well as the release of catecholamines, depends on the amount of segontin added to the samples. It is interesting to note that the ability of the granules to take up segontin is limited, since after addition of doses of segontin higher than necessary to deplete the granules completely (0.476  $\mu$ M/sample) no more segontin is taken up; consequently the molar ratio, catecholamine release/segontin uptake, remains constant and is about 23. In a further 14 experiments with various doses of segontin, and therefore various releasing effects (20–100 per cent), the molar ratio, catecholamine release/segontin uptake, was 20.5 (standard deviation, 5.26), that is, uptake of segontin is proportional to the release of catecholamines although 20 times smaller. The determination of the uptake of segontin and of the release of catecholamines in the non-incubated samples indicated that segontin is already taken up from the granules during

Fig. 1. Release of catecholamines (white) and ATP (hatched) from isolated granules by lyophilized reserpine phosphate (1  $\mu$ M/sample) and segontin lactate (0.3  $\mu$ M/sample). The samples contain in 7 ml.: 2 ml. granules from 200 mg medullary tissue, 0.1 ml. segontin or reserpine and 4.9 ml. sucrose-phosphate buffer pH 6.8. Incubation: 60 min at 37° C. Means of 4 experiments and their standard deviations

centrifugation (15 min, 0° C) while the catecholamines are released only during the following incubation at 37° C. Tyramine, on the other hand, is exclusively taken up at the same time as it releases catecholamines. Therefore, at 0° C no uptake of tyramine and no release of catecholamines take place.

From these results it is obvious that in contrast to tyramine both segontin and reserpine cause, *in vitro*, in addition to the release of catecholamines a proportionate release of ATP. The uptake of segontin, as well as the release of catecholamines, depends on the dose of segontin added. Whereas in the case of tyramine the released catecholamines are replaced by the uptake of equimolar amounts of tyramine, the uptake of 1 mole of segontin is followed by the release of about 20 moles of catecholamines. It can therefore be concluded that the mechanisms of action of tyramine and segontin are different.

We thank Farbwerke Hoechst and Ciba Basle for the supply of labelled segontin lactate and lyophilized reserpine phosphate (reserpine) respectively. This work was supported by a grant from the Deutsche Forschungsgemeinschaft.

### Metabolism of Acid Mucopolysaccharides of the Rabbit's Dermis following Skin Treatment with Irritating Substances

In the rabbit's skin chronically treated with croton oil a remarkable change is observed in the ratio between hyaluronic acid and chondroitin sulphuric acid, the former largely prevailing over the latter after one month's treatment; the same change occurs when the skin is treated with carcinogenic substances<sup>1</sup>. These data supplement what is already known about the presence of mucopolysaccharides in inflammatory processes (see, for references up to 1959, Delaunay and Bazin<sup>2</sup> and, more recently, Berenson and Dalferes<sup>3</sup>, White *et al.*<sup>4</sup>, Zonta *et al.*<sup>5</sup>). So far as we know, no data are available concerning the changes induced in the metabolism of mucopolysaccharides by those stimuli which elicit inflammation. The present work was concerned with the dynamics of the metabolism of acid mucopolysaccharides of the rabbit's skin treated for short periods of time with croton oil, evaluating the incorporation into them of glucose (as glucosamine and galactosamine).

Albino rabbits weighing 2.5–3 kg were shaved on approximately 300 cm<sup>2</sup> of the back. Half this surface was

Table 1 shows the treatments performed on each single animal and the specific activity of total hexosamines as well as that of glucosamine and galactosamine taken separately. These values were obtained from MPS extracted and hydrolysed separately from both control and treated areas of each animal's skin.

From examination of Table 1 it appears that:

(1) The activity of hexosamines obtained by hydrolysis of MPS extracted from the treated area is always stronger than that of corresponding hexosamines extracted from the control area.

(2) Such increase in activity occurs rapidly; it is, in fact, fairly evident in animals which were killed 3 h after the one treatment received.

(3) The increase in activity of glucosamine from MPS of the treated area (compared to that of the corresponding control area) is more relevant than the increase in activity of galactosamine from MPS of the treated area (still compared to that of the corresponding control area). The only exception is animal No. 1, in which the treatment was notably weaker than the average.

The results of the present work suggest that under a local irritating stimulus there is an accelerated synthesis of acid mucopolysaccharides of the dermis, and that this

C, MPS extracted from the control area.

T, MPS extracted from the skin area treated with croton oil.

\* The amount of croton oil solution administered each time was notably inferior to the average. Also the macroscopic reaction, especially in the first animal, was less severe.

† Injected with 50 µc/kg, instead of 10 µc/kg.

‡ The amount of croton oil solution was larger than that normally used. The macroscopic reaction was quite evident, with a most marked edema of both dermis and subcutaneous tissue. The activity of hexosamines of the control area is much less than average; probably the very strong treatment caused more than merely local effects.

treated, the other half was kept as control. Treatment was carried out with a 2.5 per cent solution of croton oil in acetone, dropped on the skin (about 1.5 ml. solution per 100 cm<sup>2</sup> surface). Each animal was intravenously injected with 10 µc/kg of glucose <sup>14</sup>C (U) (specific activity 3.57 mc./mmole)—except two which, as will be explained, received 50 µc/kg. The times of injection and killing are reported in Table 1. The skin was removed separately from treated and control areas, leaving between the two areas a strip about 2 cm wide. The subcutaneous tissue was mechanically removed. The skins were minced and soaked in acetone, which was replaced three times in a week. The material was then dried, and acid mucopolysaccharides (MPS) were extracted from it after digestion with papain, by the method described by Scott<sup>6</sup>. Part of the MPS extracted was hydrolysed with 5 N HCl for 7 h at 100° C, and the hydrolysate was dried. Column chromatography (0.8 × 45 cm) on 'Dowex 50 WX8', 200–400 mesh, was performed for the separation of glucosamine and galactosamine, according to Gardell<sup>7</sup>. Fractions of 3 ml. were collected. One ml. of each was used to determine the amount of hexosamine while the remaining 2 ml. were dried, and the material—recovered three times with distilled water—was placed on aluminium disks. Activity was assessed with a windowless gas-flow counter, with anti-coincidence scintillation apparatus (Alberigi-Quaranta *et al.*<sup>8</sup>).

response of the connective tissue occurs rapidly. Moreover, of the two predominant MPS of the skin, one (hyaluronic acid) contains glucosamine and the other (chondroitin sulphuric acid, especially of B type) contains galactosamine, so that one can safely conclude that the highest increase is found in the synthesis of hyaluronic acid. The inflammatory stimulus, therefore, develops its action not only by promoting an accelerated synthesis of MPS in fibroblasts, but also by directing it chiefly towards the production of hyaluronic acid. This fact may be at least partly responsible for the reported finding<sup>1</sup> concerning the change in relationship between the two MPS, observed after one month's treatment with either irritants or carcinogenic polycyclic hydrocarbons.

## HAEMATOLOGY

## Acid Deoxyribonuclease Activity in Peripheral Leucocytes of Swiss Mice

THE general morphological details of the blood cells of the common mammalian species have been thoroughly examined. Recently, increased interest in the distribution of the intracellular chemical components of these cells has suggested that cytochemical analysis of acid deoxyribonuclease activity in leucocytes of Swiss mice might prove profitable.

Recent findings on the occurrence of deoxyribonuclease in the different elements of the blood indicate that the enzyme is found in rather high concentration in the serum as well as in the cells, especially leucocytes<sup>1</sup>. Deoxyribonuclease is important in combating infectious viral nucleic acids which are not blocked by anti-serum against the intact virus. Herriot and Gupta reported that the major source of serum deoxyribonuclease is in the cellular elements of the blood. There are wide variations in reports on the concentrations of this enzyme in different cell types<sup>2,3</sup>. The platelets have been suggested as a possible source of serum DNase activity<sup>3</sup>. If this were correct, cytochemical analysis should reveal the presence of this enzyme in them, and in this investigation a cytochemical technique was applied to the investigation of this supposed source of serum deoxyribonuclease.

Blood smears were obtained from the tail of Swiss mice of the Webster strain and air dried for 10–30 min at room temperature. They were fixed for 10 min in formalin vapour. This was accomplished by adding enough 10 per cent formalin to moisten a thin layer of absorbent cotton at the bottom of a small Coplin jar which was covered with a large glass jar. Following fixation, the smears were incubated for up to 1½ h at 37° C. The

Fig. 1. Neutrophilic nucleus showing uniform distribution of enzyme activity throughout the chromatin

Fig. 2. Lymphocyte showing activity along the thin rim of the cytoplasm

Fig. 3. Reticulocyte or late normoblast with detectable granules

Fig. 4. A peripheral blood smear stained for acid deoxyribonuclease. The enzyme is demonstrated in the nuclei, especially at the nuclear membrane

incubation solution was prepared immediately before use from the stock solutions. The composition of the incubation medium was according to that described by Vorbrodt<sup>5</sup>. The staining procedure was that described by us in an earlier report. After incubation the smears were washed briefly in distilled water and placed in dilute ammonium sulphide solution for 10 min. After washing in distilled water, the smears were counterstained in 1 per cent safranin solution for 30 sec, rinsed in distilled water, dried and mounted in glycerine jelly. Photomicrographs were taken with phase contrast (oil immersion  $\times$  phase 3).

Acid deoxyribonuclease is indicated by black dye precipitated within the cells. It is consistently demonstrable in blood lymphocytes. It is also found occasionally in the nuclei of neutrophils, indicating a diffusely distributed activity throughout the chromatin structure (Fig. 1). In addition, granules, 5–10 in number, were detected in reticulocytes or late normoblasts (Fig. 3). The mature erythrocytes did not contain any detectable amount of deoxyribonuclease. Minute black granules were encountered throughout the entire periphery of the cytoplasm of lymphocytes (Fig. 2). These granules represent evidence of activity. The morphological characterization of the enzymatic activity in the form of dark granules was revealed best when examined with phase contrast microscopy.

When DNA was omitted from the incubation medium no staining occurred except for the presence of a few faintly stained black granules of some neutrophils. On the other hand, the addition of sodium fluoride (0.01 M) to the incubation medium completely inhibited the reaction.

Vorbrodt<sup>5</sup> demonstrated strong reaction in the cytoplasmic granules arranged along the bile canaliculi, and

positive reaction for DNase in the nuclei (or the nuclear membrane) and in the chromosomes of liver parenchymal cells. He also found enzyme activity in Kupffer cells, macrophages of the spleen, Novikoff hepatoma and Novikoff ascites hepatoma in the intestinal epithelium, and in the proximal convoluted tubules and nerve cells of the rat kidneys and brains, respectively. He noted that phagocytic cells generally showed a high enzymatic activity.

Acid DNase has mostly been associated with lysosomes. Considering this, the specificity of the reaction for DNase cannot be based solely on microscopic patterns, since investigation during these examinations revealed the positive reaction in the nuclei of the neutrophils. After the use of the inhibitor (sodium fluoride solution) the activity in both the neutrophilic nuclei as well as the cytoplasmic granules of the lymphocytes was lost. This was contrary to Vorbrodt's finding, the persistence of nuclear activity in spite of the addition of inhibitor  $\text{Na}_2\text{SO}_4$  in the incubation solution. He assumed that the cells of rat liver and other organs had two DNA-hydrolysing systems: one inhibited by the sulphate ions, located in the lysosomes; the other insensitive to sulphate ions in the cell nucleus. He contended that enzyme localized in the nucleus could be regarded as nucleotide phosphodiesterase or acid nuclease since positive reactions appeared when either DNA or RNA is the substrate. But this was not true of our experiments (ref. 4), since there was no hydrolysis of RNA by any kind of nuclear enzymes in any of the cell types in the peripheral blood. These two experiments suggest to us that the reaction in the peripheral leucocytes is specific for both DNase and RNase.

No enzyme activity was found in the blood platelets, which Herriot, Connolly and Gupta considered to be a major source of serum DNase in human blood. Only the lymphocytes showed the cytochemical activity and nuclei of some of the neutrophils.

### Hæmoglobin N of Sheep

In a previous publication<sup>1</sup> the finding of a new type of sheep hæmoglobin was reported. This has a slower rate of migration on starch gels than the A and B hæmoglobins. It was first found in highly anæmic lambs where its relative amount of total hæmoglobin showed great variation. For these reasons it was called abnormal and tentatively given the symbol N. Blunt and Evans<sup>2</sup> reported a new hæmoglobin in sheep with hæmoglobin A type and made anæmic by experimental bleedings. This new type was electrophoretically similar to hæmoglobin B.

This communication deals with results from further investigation of the N hæmoglobin. It has been investigated by use of starch-gel electrophoresis, and its position in relation to the normal sheep hæmoglobins A and B is shown in Fig. 1, which is a photograph of a gel stained with benzidine.

Three of the six samples have the N hæmoglobin. Two of these have the A hæmoglobin in addition to the N hæmoglobin, and the third has the three hæmoglobins A, B and N. It can also be seen that of the two samples with A and N the N band is much stronger in one of them.

We have in the winter and spring of 1964 investigated 762 sheep living in Norway of which 130 were lambs. They represent five different breeds. In Old Norwegian sheep ('Spæl'), which is a rather primitive short-tail type, the N hæmoglobin was found in 99 of 105 investigated ewes. These were all of type hæmoglobin AA. It is, however, very weak in most of the samples. In two other native Norwegian breeds (Dala and Rygja) the N band even though not so frequent was commonly occurring, and also in the Cheviot breed which is based on original imports from Great Britain. Samples from 56 Oxford-down sheep of which 15 were AB and 41 BB did not reveal any N hæmoglobin. From Spain we received 59 samples of which 6 were AA, 25 AB and 28 BB. The N hæmoglobin was, however, found in one AB animal only.

The majority of our samples came from ewes, but the N hæmoglobin has been observed in rams and lambs also. The youngest lamb in which hæmoglobin N was observed was 10 days old. Accordingly it has been found together with fetal hæmoglobin.

One of the most typical features of the N hæmoglobin is its variation. Its migration rate relative to the A and B hæmoglobins on starch gels is, however, always the same. It is most often observed in AA animals and has never been found in animals of phenotype BB. Usually it is very faint, the percentage of total hæmoglobin being less than one. Animals having a higher percentage of N hæmoglobin are usually anæmic. The highest percentage of N hæmoglobin which has been observed was in an animal having a hæmoglobin content of 2.4 g/100 ml. In this sheep the total hæmoglobin was composed of approximately 80 per cent N hæmoglobin and 20 per cent A hæmoglobin. Three- to four-week-old lambs of phenotypes AA and AB usually had a rather high proportion of N hæmoglobin (10-30 per cent).

Even though the N hæmoglobin is not regularly detectable we are now inclined to consider it to be more normal than abnormal. In this connexion the similarity to the A<sub>2</sub> hæmoglobin in man may be mentioned, where this component may increase in the anæmic condition called thalassæmia minor, although to a much lesser extent<sup>3</sup>. Because of this resemblance and its occurrence in a high percentage of Old Norwegian sheep, we favour a similar genetic theory as for A<sub>2</sub> in man, where Ceppellini<sup>4</sup> suggested that the gene for the  $\delta$  chain of A<sub>2</sub> hæmoglobin was linked to the gene for the  $\beta$  chain. Accordingly our hypothesis is that one of the structural genes controlling N hæmoglobin is closely linked to one of the structural genes controlling the A hæmoglobin. Why the gene for the N hæmoglobin apparently usually is 'turned off' is for us a question difficult to answer at present, although several theoretical explanations might be given.

### Hæmoglobin O<sub>Arab</sub> in Bulgaria

SEVERAL cases of moderately severe hypochromic hæmolytic anaemia have recently been observed in Burgas, Bulgaria<sup>1</sup>. The affected individuals were unrelated white adult men and women. They showed splenomegaly, slight icterus, decreased osmotic fragility of the red cells and 40–90 per cent target cells. Paper and starch-gel electrophoresis<sup>2</sup> at pH 8.6 of their hæmoglobin showed complete absence of normal adult hæmoglobin (Hb A) and presence of a slow-moving abnormal hæmoglobin. The electrophoretic mobility of this abnormal hæmoglobin was similar in paper electrophoresis to that of hæmoglobin C (Hb C). In starch-gel electrophoresis the abnormal hæmoglobin moves slightly ahead of Hb C. In agar-gel electrophoresis at pH 6.0<sup>3</sup> it moved between Hb A and Hb C, in the position of hæmoglobin S (Fig. 1).

The abnormal hæmoglobin of the anæmic individuals was examined by 'fingerprinting', following the method of Ingram<sup>4</sup> as modified by Baglioni<sup>5</sup>. The hæmoglobin of the individuals A II-1, B II-3, B II-4, C II-2 and D I-1 of Fig. 2 gave an identical fingerprinting pattern. Peptide

Fig. 1. Agar-gel electrophoresis at pH 6.0 of the hæmoglobin of an individual (A I-2) heterozygous for the Hb O<sub>Arab</sub> gene (left). Hæmoglobins A and L (centre) and F (right) are shown for comparison.

$\beta TpXIII$  (ref. 5) was absent from the position that it occupies in the fingerprint of Hb A and was moved to a more cathodic position. The fingerprinting pattern obtained (Fig. 3) was identical to that described by Baglioni and Lehmann<sup>6</sup> for hæmoglobin O<sub>Arab</sub> (Hb O<sub>Arab</sub>). The abnormal hæmoglobin observed in the affected individuals was thus identified with Hb O<sub>Arab</sub>: this hæmoglobin has shown a glutamic acid to lysine substitution in residue 121 of the  $\beta$ -peptide chain<sup>6</sup>.

The families of four affected individuals have been thoroughly investigated; less-complete information has been collected on the family of one more individual affected by the same type of anaemia. The family trees of the four propositi investigated are reported in Fig. 2. In the families A, B and C one of the parents of the propositus was shown to be a carrier of Hb O<sub>Arab</sub>, while the other parent was found to be a thalassaemia-trait

Fig. 2. Family trees of individuals affected by severe hypochromic hæmolytic anaemia (indicated by arrows). These individuals are  $\beta^{OAr}/\beta^{Thal}$  heterozygotes.

carrier. Thalassaemia is relatively frequent in some regions of Bulgaria, which have been infested by malaria in the past<sup>1</sup>. The combination of the thalassaemic gene with the Hb O<sub>Ar</sub> gene in the propositi causes the absence of normal haemoglobin and the moderately severe anaemia. The thalassaemic gene of the families investigated behaves as a gene allelic to the  $\beta^{0Ar}$  gene and it is thus a  $\beta$ -thalassaemic gene<sup>7</sup>. The propositi are very likely heterozygotes for the  $\beta$ -thalassaemic gene and for the  $\beta^{0Ar}$  gene ( $\beta^{Thal}/\beta^{0Ar}$ ). Not enough information has been obtained on family D (Fig. 2) to ascertain whether the propositus I-1 is also heterozygote for thalassaemia or whether he is homozygote for the  $\beta^{0Ar}$  gene. The haematological picture of this individual is extremely similar to that of the propositi of the other families, and it thus seems likely that his genotype is identical to that of the other propositi.

The occurrence of Hb O<sub>Ar</sub> in Bulgaria is of genetic and ethnological interest. Hb O<sub>Ar</sub> has so far been described in one Arab family only, observed in Israel<sup>8</sup>. It may be supposed that the Hb O<sub>Ar</sub> gene has been imported into Bulgaria during the five centuries of Turkish rule or more recently when a part of the Bulgarian population of the district of Burgas emigrated from the European part of Turkey (eastern Thrace) during 1912. Two of the families examined have indeed come from Eastern Thrace. However, Hb O<sub>Ar</sub> has not yet been reported to occur in Turkey. It seems more likely that Hb O<sub>Ar</sub> has appeared in Bulgaria as the result of an independent mutation. This mutation might have been preserved under the influence of severe malaria selection; other hereditary haematological disorders, like thalassaemia and favism, are quite common in the region of Burgas<sup>1</sup>.

Fig. 3. Fingerprint of the Hb O<sub>Ar</sub> present in the individuals affected by severe hypochromic hemolytic anemia. The arrow indicates the abnormal peptide  $\beta^{0}T\text{pXIIIb}$ , where a lysine substitutes a glutamic acid residue.

Further investigations into the distribution of Hb O<sub>Ar</sub> in other regions of Bulgaria are needed. If Hb O<sub>Ar</sub> is found there also, the theory of an independent mutation will acquire further support. If Hb O<sub>Ar</sub> is found in those regions where malaria was widely spread, the selection of the  $\beta^{0Ar}$  gene by malaria may be considered likely. Malaria may possibly select all those mutations affecting red cell metabolism and/or haemoglobin, which by local circumstances are available. If further investigations show that the diffusion of the  $\beta^{0Ar}$  mutation is limited to the district of Burgas, very near to Turkey, the 'import' theory may gain some likelihood.

## PATHOLOGY

### Recovery of Mycoplasmas in the Study of Human Leukemia and Other Malignancies

NUMEROUS reports have been published concerning the necessity of testing for the presence of mycoplasmas before the interpretation of experiments performed in cell cultures<sup>1-3,6</sup>. Such tests are especially important when the presence of viruses is suspected, since recent evidence indicates that some mycoplasmas are capable of eliciting a transmissible cytopathic effect<sup>4-7</sup>.

In addition, some mycoplasmas and viruses share properties, such as size, filterability, morphology in electron microscopy, sensitivity to ether, ability to haemagglutinate and cause haemadsorption, interference with virus replication *in vitro*, lack of inhibition by certain commonly used antibiotics and inhibition of growth by homologous antiserum. Thus, the absence of ordinary bacteria and moulds in preparations eliciting a cytopathic effect in cell cultures is an unreliable criterion for viral identification. Great caution should be exercised in classifying new agents as viruses, especially as myxoviruses, without adequate testing to exclude their identity as mycoplasmas.

The problem posed by the similarity of mycoplasmas to viruses is exemplified by a consideration of the properties of several agents isolated during work on human malignancies<sup>8,11-13</sup>. One of the more thoroughly investigated isolates is that reported by Negroni<sup>8</sup>, who obtained an agent while examining human leukemic bone marrows. These preparations were inoculated into tissue cultures of whole human embryos or kidneys. A 'virus' was isolated from each of ten cases and became cytopathic for the cells in the course of serial passage. Comparable cultures inoculated with bone marrow from control cases showed no such effect. Negroni concluded that the results did not justify any statement regarding the relationship of these viruses to leukemia itself, but that "the frequency of the association is, however, remarkable".

The Negroni agent was obtained from Dr. Negroni independently by our two laboratories (Wistar Institute and Laboratory of Infectious Diseases, National Institutes of Health) as a 0.2-ml. volume of infectious fluid from human embryo cells and the same results were obtained. Direct introduction of the material on mycoplasma agar of Hayflick's formula<sup>9</sup> revealed mycoplasma at a concentration of 10<sup>8</sup> colony-forming units/ml. The organism was gently scraped from agar into Eagle's basal medium containing penicillin as the only antibiotic. This infectious fluid and control fluid prepared from an uninoculated agar plate were introduced into tube cultures of primary human embryonic kidney and primary African grivet monkey kidney containing either chlortetracycline ('Aureo-

mycin', Lederle) (25 µg/ml.) or penicillin (100 units/ml.). In addition, the isolate was sub-cultivated for twelve passages on agar medium and then inoculated into similar cultures. The results presented in Table 1 indicate that the mycoplasma isolates caused a cytopathic effect in human embryonic kidney and grivet monkey kidney which could be inhibited by chlortetracycline but not by penicillin. Although human embryonic kidney was more sensitive as demonstrated by the earlier appearance of the transmissible cytopathic effect, grivet monkey kidney was also susceptible. Since the 12th agar passage, representing a dilution of approximately  $10^{-15}$  of the original isolate, caused a similar cytopathic effect, it is doubtful that a virus was present in the original fluid which was responsible for the cytopathic effect. This notion was further supported by evidence that fluid from the original Negroni agent sample was cytopathic for human embryonic kidney only in the absence of chlortetracycline.

Table 1. CYTOPATHIC EFFECTS IN TISSUE CULTURES PRODUCED BY MYCOPLASMAS ISOLATED FROM PREPARATIONS OF THE NEGRONI AGENT

Cell culture	Passages on agar	Cytopathic effect with mycoplasma isolate		Washing from sterile agar (control)

Human embryonic kidney	0*	—	++	—
	1	—	+	—
Grivet monkey kidney	1	—	+	—
	12	—	+	—

\* Sample as obtained from Dr. G. Negroni

It was of interest to attempt to identify this mycoplasma with those of known human origin, and serological investigations were undertaken. The procedure used for the complement-fixation test was described previously<sup>10</sup> and utilized a broth-grown antigen concentrated 90-fold by centrifugation. This preparation was treated with guinea-pig complement for 60 min at 37° C followed by 30 min at 56° C in order to remove anti-complementary activity. This antigen was found to be non-reactive when tested against 4 units of antisera prepared against the known species of human mycoplasma: *Mycoplasma hominis*, type 1, *M. hominis*, type 2, *M. pneumoniae*, *M. fermentans*, *M. salivarium* and *M. orale*. The absence of complement-fixing reactivity in this test does not conclusively distinguish this agent from the known human mycoplasma species. A definite determination must await the outcome of investigations performed with homologous antisera prepared against the new isolate. Also, the antigen was non-reactive with antisera prepared against many of the mycoplasma species of animals, including *M. mycoides* var. *capri*, *M. gallisepticum* and *M. gallinarum*. Finally, antisera to the agent, kindly supplied by Dr. Negroni, give a positive reaction in the growth inhibition test with the mycoplasma isolated by us.

In addition to the agent described by Negroni<sup>6</sup>, four other agents recovered in the course of investigations of human malignancy have been identified as mycoplasmas<sup>11-13</sup>. Employing techniques described here, two of these<sup>11</sup>, studied more extensively at the Wistar Institute, were recovered repeatedly during investigations with two human tumours (haemangioma and retropharyngeal fibroma). These two strains of mycoplasmas as well as the others already mentioned here<sup>12,13</sup> share with the Negroni agent the characteristic of producing cytopathic effects in tissue culture. Some lack antigenic identity in complement-fixation tests with known human mycoplasma species. Similarly, some of these agents and the Negroni agent were capable of fermenting glucose, a property of human mycoplasmas shared only with *M. pneumoniae* and *M. fermentans*.

Thus, a group of previously unclassified mycoplasmas have been isolated from human malignancies as well as from normal tissue culture systems<sup>5,14</sup>. The significance of these findings relevant to human ecology is difficult to assess at present.

This investigation was supported (in part) by research grant CA-04523 and contract PH-43-62-157 from the National Cancer Institute, U.S. Public Health Service, to the Wistar Institute, and by U.S. Public Health Service career development award 5-K3-CA-5938 to one of us (L. H.). We thank Miss Nancy L. Pleibel and Miss Rose S. Grady of the Wistar Institute for their assistance. Miss Audrey G. Newnham of the University of Cambridge kindly supplied the animal mycoplasma antisera.

## A Rapid Technique for detecting Multiple Antigen-Antibody Precipitin Reactions

USING standard immunoelectrophoretic techniques in gelatin<sup>1</sup> or on cellulose polyacetate<sup>2</sup>, the minimum time for an indication of multiple antigen-antibody precipitin reactions is from a few hours to two days. Even various gelatin diffusion techniques<sup>3-5</sup> may take from a few hours up to 22 days<sup>6</sup>. The need for a rapid means of detecting multiple antigen-antibody reactions as evidence of antigen homogeneity or heterogeneity is therefore apparent.

The gelatin electrophoretic technique of Bussard<sup>7</sup>, in which antisera are placed closer to the anode, antigen closer to the cathode, relies on endosmotic flow to carry the  $\gamma$ -globulin toward the advancing protein antigens. This technique is rapid, but, as with most gelatin techniques, is time-consuming in preparation and preservation of results. The 'crossing paper' electrophoretic technique of Nakamura and Ueta<sup>8</sup>, in which antisera are placed closer to the anode and antigen closer to the cathode at oblique angles to each other on filter paper, takes at best 8 h to detect precipitin arcs.

Realizing that  $\gamma$ -globulin migrates relatively slowly under electric current, the 'crossing paper' technique was modified and adapted for use with cellulose polyacetate electrophoretic support strips (Gelman's 'Sepharose III' strips, 1 in.  $\times$  6  $\frac{3}{4}$  in.; Ann Arbor, Mich.).

A veronal-barbital buffer, pH 8.6, ionic strength 0.05, is used routinely in a home-made electrophoretic chamber. One drop (about 5  $\mu$ l) of antisera (anti-fetal bovine sera prepared in rabbits) is applied to the strip 1 in. from the cathode, 4 in. from the anode, and electric current of 250 V, 5-7 m.amp current is passed for 30 min, permitting the antisera components to align and begin to separate. Then the antigens (fetal bovine serum diluted 1:20 in buffer) are applied as a straight line with a

Fig. 1. (a) One drop of antisera (Ab) applied at the start. Antigens (Ag) applied as a straight line 30 min later. (b) The antigens passing through the  $\gamma$ -globulin. Strip stained without rinsing. (c) Strip stained after 10-min rinse in saline. Three precipitin arcs are visible

capillary tube immediately behind (closer to the cathode) the point of antisera application (Fig. 1a). Current is restored for 20 min. The antigens migrate through the  $\gamma$ -globulin and precipitate arcs form where equivalent proportions are reached (Fig. 1b). At the end of that time, the strip is removed to 0.85 per cent saline and allowed to rinse for 10 min. The strip is then blotted, dried at 37° C for 10 min, stained for 5 min in Ponceau S stain and rinsed in 5 per cent acetic acid following Gelman's instructions. From our test system we can identify at least three precipitin arcs (Fig. 1c). The entire procedure, to a permanent mount between two glass slides (cleared with mineral oil, if so desired), takes less than 2 h.

For illustrative purposes and to verify that multiple antigen-antibody reactions are indeed occurring in the test system, the same system was analysed immunoelectrophoretically on cellulose polyacetate (Oxoid, Colab, Chicago, Ill.) as described by Kohn<sup>2</sup>. The antigens were separated electrophoretically and antisera allowed to diffuse toward them. Three distinct antigen-antibody reactions were identified, which verifies the results presented (Fig. 2).

The procedure described here is effective so long as all the antibodies are contained in the slow-moving  $\gamma$  portion of the antiserum, such as with rabbit serum<sup>3</sup>, and provided the slowest-moving antigen will reach the  $\gamma$ -globulin in the time allotted. Although this technique lacks the specificity of standard immunoelectrophoretic techniques,

Fig. 2. Antigens (Ag) separated electrophoretically. Antisera (Ab) diffused toward them. Three precipitin arcs are visible

due to crowding of multiple bands, it is a rapid means of determining the existence of antigen-antibody precipitin reactions occurring in any given system. Where few antigen-antibody reactions occur, it does reflect specificity plus the advantage of speed.

### Esterase Studies on Dog Mast-cell Tumours

RECENTLY our laboratory reported the isolation of proteolytic enzymes from a dog mast-cell tumour using DEAE-cellulose and CM-cellulose columns. An esterase which split *N*-acetyltyrosine ethyl ester (ATEe) and another which split *p*-toluene sulphonyl-L-arginine methyl ester (TAME) were described<sup>1</sup>. Using column chromatography and eluting with a concentration gradient of phosphate buffer with a pH of 8.0, several peaks of ATEe esterase and two TAME esterase peaks were found. All the peaks of ATEe esterase have since been found to have a similar Michaelis constant (*K<sub>m</sub>*) of 1.0–1.5 mM, except one which had a *K<sub>m</sub>* value of about 4 mM. From these observations the different peaks of ATEe esterase with similar *K<sub>m</sub>* values were postulated to be one enzyme.

In the present study we have shown the existence in dog mast-cell tumours of one

strong peak of ATEe esterase and one TAME esterase peak when eluted with a sodium chloride concentration gradient from a DEAE-cellulose column (Fig. 1). From these data it is apparent that the many peaks obtained by means of a concentration gradient of phosphate buffer (pH 8) indicate only minor differences in the enzyme molecule.

The mast cells used in this study were obtained from the mast-cell tumours of four dogs. The data presented are from one representative sample. Diagnosis on all tumours was established by histological examination.

The tissue was homogenized in a Potter Elvehjem homogenizer in cold 0.01 M phosphate buffer, pH 7.5. The supernatant fluid was suspended in a 40 per cent saturation of ammonium sulphate and then centrifuged. The supernatant was then dialysed against 0.005 M potassium phosphate buffer with a pH of 7.5 at 4° C for 48 h. The DEAE-cellulose column (1.2 × 20 cm) was equilibrated with 0.005 M potassium phosphate buffer (pH 7.5). The sample containing 86 mg of protein was applied to the column and then 20 ml. of 0.01 M phosphate buffer (pH 7.5) was added. The elution was performed with a linear concentration gradient of NaCl. The elution was initiated with 0.01 M potassium phosphate buffer (pH 8) and no NaCl, and increased linearly until the concentration of NaCl was 1 M in the same buffer. A total elution volume of 400 c.c. was used. The effluent fluid was collected in 10-c.c. samples and the protein content measured in a spectrophotometer at the optical density of 280 mμ. The proteolytic enzyme content of each tube was assayed by casein digestion at a pH of 7.6 (ref. 2). One unit of casein digestion was defined as that quantity of enzyme which produced an increase in trichloroacetic acid-soluble products of 10<sup>-3</sup> optical density units in digestion for 30 min by 1 ml. of the sample. ATEe- and TAME-esterase activities were assayed on a pH-stat (Radiometer, Copenhagen). The hydrolysis of each substrate was determined on 0.2 ml. of the test sample at room temperature. The pH was held constant at 7.9 by the continuous addition of 0.1 N sodium hydroxide for at least 10 min. A unit of enzyme was defined as that amount of enzyme which hydrolysed 1 μmole of substrate in 1 min (ref. 1).

Fig. 1. DEAE-cellulose column chromatography of dog mast-cell tumour. Each tube contains 10 ml.

It was found that the ATEe-esterase was eluted around 0.4 M NaCl and the TAME-esterase at a slightly higher molarity. Each esterase showed only one peak. The tubes showing significant activity (Nos. 15–18 and 19–22, Fig. 1) were dialysed with 0.005 M potassium phosphate buffer (pH 7.5) at 4° C for 48 h and then re-applied to the DEAE-cellulose column and eluted by the same method as that described above. Although similar patterns for ATEe-esterase and TAME-esterase were again obtained, some of the TAME-esterase activity was lost. Varying the pH at which the sample was initially applied to the column over a range of 6.5–7.8 revealed a good recovery of ATEe-esterase throughout this range, but the best recovery of TAME-esterase occurred when the procedure was started at pH 7.4–7.5. At lower pH, 6.5–7.2, it was possible to obtain ATEe-esterase fractions without TAME-esterase activity. We have been unable, however, to obtain TAME-esterase activity without ATEe-esterase activity by changing the pH of application and/or elution.

Three additional dog mast-cell tumours were treated similarly by a linear concentration gradient of NaCl. These neoplasms showed similar ATEe-esterase and TAME-esterase activity to the one described in detail above. In an occasional tumour, however, a weak ATEe-esterase was eluted when the NaCl concentration was around 0.05 M. The separation of ATEe- and TAME-esterases in these three tumours was again found to be incomplete. Each dog, and different neoplasms obtained from the same animal, had a wide variation of both the enzyme content and specific activity, but all the mast-cell tumours showed a similar elution pattern which indicates similar enzymes.

From these results we conclude that in dog mast-cell tumours one strong ATEe-esterase and one TAME-esterase exist and are clearly different enzyme molecules. In addition, one weak ATEe-esterase may exist in dog mast-cell tumours.

## IMMUNOLOGY

### A Radioimmunoassay for Human Chorionic Gonadotrophin

A NUMBER of immunological assay methods for human chorionic gonadotrophin (HCG) have been described recently. These include haemagglutination<sup>1</sup>, latex particle agglutination<sup>2</sup>, and complement fixation<sup>3</sup>. These methods have been devised principally to detect or confirm pregnancy, and qualitative tests are usually adequate for this purpose. Patients with untreated choriocarcinoma excrete HCG in the urine. During the treatment of these patients with anti-metabolite drugs the concentration of HCG in the body fluids, which provides an index of the tumour's behaviour, falls rapidly to low levels. In these circumstances an assay method which is both more precise and more sensitive is needed. With this objective a radioimmunoassay technique, similar to that described by Hales and Randle for insulin<sup>4</sup>, has been applied to HCG.

HCG-antibody complexes normally give a heavy precipitate; but at the low concentrations of reagents required to give a sensitive assay the complexes are soluble. These soluble complexes can be precipitated by the addition of anti-γ-globulin serum and they can then be filtered off on Oxoid filter membranes. When HCG labelled with iodine-131 is included in the system the radioactivity recovered on the membrane is related to the concentration of unlabelled HCG present.

Antiserum to HCG was prepared in rabbits using a crude preparation of the hormone (2,000 i.u./mg) with Freund's complete adjuvant. Horse anti-(rabbit γ-globulin)—a gift from Dr. A. J. Fulthorpe, Wellcome Research Laboratories—was used as the precipitating antiserum.

Highly purified HCG (10,000–12,000 i.u./mg) was prepared from the urine of patients with choriocarcinoma by methods which will be described elsewhere. This preparation was labelled with iodine-131 by the method which Greenwood, Hunter and Glover<sup>5</sup> used for human growth hormone to give an activity of 140–170 μc./μg.

Assays were performed by the addition of HCG  $^{131}\text{I}$  to HCG standards and to serial dilutions of the unknown specimen. These were incubated with anti-HCG serum at  $2^\circ\text{C}$  in a total volume of 0.3 ml. and all dilutions were made in 0.04 M phosphate buffer pH 7.0 + 0.4 M sodium chloride. After 4 h, 0.1 ml. anti- (rabbit  $\gamma$ -globulin) serum was added and the incubation was continued for periods of 18 h–5 days depending on the concentrations of antisera used.

The concentrations of antisera for use in the assay were determined by previous titration to find the region of slight antigen excess. In a titration of HCG antiserum in the presence of 250  $\mu\text{g}$  of labelled HCG using the precipitating antiserum at a dilution of 1:20 and an 18-h second incubation, 60 per cent of the added label was precipitated in the antibody excess zone. Using an HCG antiserum dilution of 1:6,400 (slight antigen excess) 45–50 per cent was precipitated. These recoveries could be increased by longer incubations, but this was not necessary for practical purposes. In the assay it was found that the percentage of HCG  $^{131}\text{I}$  which was precipitated was progressively reduced by the addition of unlabelled HCG and showed a linear relationship to the log of the (unlabelled) HCG concentration (Fig. 1a).

Fig. 1. Standard assay curves for HCG. Effect of unlabelled HCG on recovery of  $^{131}\text{I}$ -labelled HCG in precipitate (100 per cent = recovery with no added unlabelled HCG). (a) Anti-HCG serum added at a concentration of 1:6,400, precipitating antiserum at 1:20; second incubation of 1 day. (b) Anti-HCG serum 1:25,000, precipitating antiserum 1:80; second incubation of 4 days. 250  $\mu\text{g}$  labelled HCG added in each case.

Attempts to increase the sensitivity of the assay by lowering the concentrations of all the components were successful, but at low concentrations of labelled HCG the precision was inadequate because of low count rates in the precipitate. It was found that with fixed concentrations of antisera an increase in the amount of labelled material did not result in any loss of sensitivity. This showed that the system did not follow the principles of isotope dilution. This appeared to be because there was a considerable range where further addition of HCG resulted in a greater total uptake of the hormone in the precipitate. In practice the sensitivity could be increased without loss of precision by reducing the concentration of antisera relative to the amount of labelled HCG if the incubation times were increased.

In this way two different ranges of sensitivity have been established (Fig. 1) and concentrations down to 0.06 I.U./

ml. HCG can be detected. The method is therefore considerably more sensitive than previously published methods and it is possible that this sensitivity could be increased still further. Preliminary assays on extracts from the urine of choriocarcinoma patients excreting HCG have been in good agreement with the results from other assay methods.

### Effect of Purinoyl Human Serum Albumin on Transplanted Ehrlich Ascites Tumour in Mice

PURINOYL human serum albumin elicits in rabbits purine-specific antibodies which also cross-react with single-stranded deoxyribonucleic acid<sup>1</sup>. It seemed of interest to investigate the effect of this antigen on tumour-bearing animals.

Purinoyl human serum albumin (Pu-HSA) was prepared by a modification of a procedure described earlier<sup>2</sup>: 6-Trichloromethyl purine (10 mg) and human serum albumin (HSA) (fraction V, Magen David Adom, Israel) (120 mg) were stirred together in water (15 ml.) at pH 9–9.5 for 2 h at  $25^\circ\text{C}$ . The resulting solution was first dialysed against tap water (24 h), then against distilled water (24 h) and then used immediately without further processing. The ultra-violet absorption spectrum of the product indicated the presence of 14 purinoyl groups per mole protein (mol. wt. 70,000).

Diploid Ehrlich ascites tumour cells ( $1 \times 10^7$ ) grown for eight days in the peritoneal cavity of female white Swiss mice (7–8 weeks old, 20–25 g) were incubated with gentle shaking for 1 h at  $37^\circ\text{C}$  with Pu-HSA (1.00 mg) in 2 ml. phosphate buffer-saline solution (PBS, M/60; pH 7.4). Cell viability was then determined by the trypan blue adsorption method. Cell mortality (5–10 per cent) was the same for cells incubated with HSA or with PBS alone.

An inoculum consisting of  $10^6$  cells + 100  $\mu\text{g}$  Pu-HSA was then administered intraperitoneally to each of a group of female mice. Animals in the control group were inoculated with  $10^6$  cells + 100  $\mu\text{g}$  HSA. In both groups tumour was established almost at the same rate in nearly all the animals. However, tumour regression occurred in some of the animals that had received Pu-HSA. The results of these experiments are given in Table 1 (Exps. 1 and 2).

In a modified experiment, mice were injected intraperitoneally with  $3 \times 10^5$  tumour cells and, 2 h later, with 500  $\mu\text{g}$  Pu-HSA. Two successive booster doses of Pu-HSA, 500  $\mu\text{g}$  each, were then given, on the second and fourth day following the initial injection. This treatment, too, had no effect on the establishment and growth of the tumour, but regression occurred in a number of mice (Table 1, Exp. 3).

The growth rate of tumour cells in animals inoculated with  $10^6$  cells and treated with 100  $\mu\text{g}$  Pu-HSA was compared with controls treated with 100  $\mu\text{g}$  HSA. This was done by counting the tumour cells on various days following inoculation. The results show that Pu-HSA

Exp. 1 and Exp. 2: Animals inoculated with  $10^6$  tumour cells + 100  $\mu$ g Pu-HSA. Exp. 3: Animals inoculated with  $3 \times 10^6$  tumour cells, followed by three successive injections, 500  $\mu$ g each, of Pu-HSA. (a) Not determined. (b) This figure includes 3 solid tumours.

had no apparent inhibitory effect during the logarithmic phase of growth (first nine days).

The total uptake of Pu-HSA (adsorbed + ingested) by the tumour cells was also studied. Tritiated 6-trichloromethylpurine (10 mg = 1.38 mc.) was coupled to HSA and the labelled protein (1.00 mg = 40,200 c.p.m.) was incubated with  $1 \times 10^7$  cells in 2 ml. PBS solution. After 1 h at 37° C, the cells were centrifuged, washed twice with PBS solution and resuspended in 1 ml. PBS solution. This suspension gave a reading of 1,960 c.p.m. in a Tri-Carb liquid scintillation counter, model 500 B, roughly corresponding to  $4 \times 10^7$  protein molecules per cell, most probably adsorbed on the cell membrane<sup>2</sup>. According to Ryser, a sphere of the size of an ascitic tumour cell would be completely covered by an albumin monolayer consisting of  $3.7 \times 10^7$  molecules. Since the value obtained is about two orders of magnitude larger than that reported for  $^{125}$ I-HSA under comparable conditions<sup>2</sup>, it seemed of interest to investigate the uptake of Pu-HSA *in vivo*. After an incubation period of 1 h at 37° C, a mixture of tumour cells ( $10^6$ ) and tritiated Pu-HSA (100  $\mu$ g = 4.25 c.p.m.) in 0.2 ml. PBS solution was injected intraperitoneally to mice. For the next five days, two animals were killed daily, the tumour cells counted and the radioactivity contents of these cells determined.

The results show that at no time was the uptake of Pu-HSA by the cells higher than 6 per cent of the quantity injected, irrespective of cell number which reached the value of  $2.8 \times 10^7$  at the end of five days. Although the radioactivity level of the preparation was somewhat too low for autoradiography, this was nevertheless attempted in order to reveal the possible concentration of the label in particular cells. The results, however, were negative.

In view of these results, it is concluded that tumour regression is the outcome of a delayed action of Pu-HSA either on the tumour cells or on the host: (a) Pu-HSA is not toxic to the cells *in vitro*; (b) it does not inhibit cell growth *in vivo*; (c) cells from a regressing tumour are still capable of establishing a new tumour by transplantation.

This investigation was supported by U.S. Public Health Service research grant CA 06996-01 from the National Cancer Institute. We thank Dr. A. Bendich, of the Sloan-Kettering Institute for Cancer Research, for the supply of tritiated 6-trichloromethylpurine and Dr. M. Aronson for his interest and advice.

## Reticulo-endothelial Function in Thymectomized Rats

ANIMALS thymectomized at, or shortly after, birth show a decreased ability to develop a normal immune response. This is manifested by an impaired ability to reject homografts<sup>1-3</sup> and heterografts<sup>1,3</sup> and a lowering of the levels of circulating antibody to various antigens, both soluble and particulate<sup>1,3-5</sup>. This failure to develop immunological maturity possibly results from the loss of a major source of lymphoid cells, to be seeded in peripheral lymphoid organs, or the loss of the source of a humoral factor which would permit existing lymphoid tissue to participate in the immune responses<sup>5</sup>.

The role of the reticulo-endothelial system (RES) in the immune mechanism has been reviewed by Thorbecke and Benacerraf<sup>6</sup>. Work in this laboratory has shown that alterations in RE function are associated with corresponding changes in antibody formation to a particulate antigen<sup>7</sup>. These studies also indicated that the induction of RE depression is associated with a reduction in the immune response to a particulate antigen essentially equivalent to splenectomy, thymectomy, and partial lymphadenectomy<sup>8</sup>. In view of these observations, and recent studies which have indicated that macrophages interact with potential antibody cells<sup>9</sup>, the immune defect in thymectomized animals could well reflect an alteration in phagocytic function. Indeed, recent studies by Osoba and Miller<sup>10</sup>, and Levey *et al.*<sup>11</sup>, demonstrate that the humoral factor elaborated by the thymus is derived not from lymphoid cells but from reticular cells.

One- to four-day-old Holtzman rats were thymectomized according to the method of Janković *et al.*<sup>4</sup>. Sham-operated litter mates were treated identically except that the thymus was left in place.

At 8-12 weeks of age, the phagocytic activity of the RES of the thymectomized and sham-operated rats was evaluated by measuring the intravascular removal rate of colloidal carbon<sup>12</sup> (Günther Wagner, Hanover, Germany; preparation C11/1431a). Each rat received an intravenous injection of 8 mg of colloidal carbon/100 g body-weight. A series of tail blood samples of 0.01 ml. were obtained from the tail veins and hemolysed in 0.1 per cent Na<sub>2</sub>CO<sub>3</sub>. The colloidal carbon concentration was determined spectrophotometrically and the half-time (*t*/2) was calculated. The absence of thymic tissue in thymectomized rats was verified.

As observed by Janković *et al.*<sup>4</sup>, the rats which were thymectomized at birth or shortly thereafter gained weight normally (Table 1). In similar confirmation, the spleen weight was not changed in thymectomized rats when compared to control animals.

Table 1. PHAGOCYTIC FUNCTION IN SHAM-OPERATED AND THYMECTOMIZED RATS

Group	Final body-weight (g)	Organ weight (g)			Colloidal carbon removal ( <i>t</i> /2 min)
		Liver	Lung	Spleen	
Thymectomized	234 ± 20	9.17 ± 0.78	1.52 ± 0.23	0.56 ± 0.05	11.6 ± 1.0
Sham-operated	220 ± 10	8.31 ± 0.31	1.47 ± 0.23	0.48 ± 0.03	10.0 ± 1.3

Values are expressed as means ± standard errors and are derived from 10 rats/group.

The phagocytic activity of the RES, as evaluated by the removal rate of colloidal carbon, was not altered in the thymectomized group. The maintenance of normal phagocytic activity following thymectomy is in basic agreement with the observation of Waksman *et al.*<sup>13</sup> that no histological abnormality in RE cells followed thymectomy. The increased susceptibility to intercurrent infection previously observed in thymectomized rats<sup>4</sup> cannot be related to an impaired phagocytic activity.

Recently the role of the macrophage in antibody formation has been predicated. This involves the essential

phagocytosis of the antigen<sup>6,14</sup> followed by transfer of cytoplasmic content as RNA or an RNA-antigen complex<sup>14</sup>. The demonstration of a direct cytoplasmic connexion between macrophages and antibody producing cells further established this concept<sup>9</sup>. Since no change in the RE function was apparent on the removal of the thymus, it is apparent that alterations in phagocytic activity of the RES are not involved in the immunological defects which follow neonatal thymectomy. The possible influence of thymectomy on other metabolic activities of the macrophage system remains to be established.

### Immune Response induced by RNA-Immuno-carrier extracted from Heterologous Immune Sera

THE importance of nucleoproteins in antibody-globulin production is well known<sup>1,2</sup>. In previous experiments<sup>3,4</sup> an evident increase of the content of RNA in the  $\gamma$ -globulin fraction in immune sera has been observed. The RNA extracted from the serum of immunized rabbits is capable of eliciting in normal rabbits the production of antibodies against the same antigens used for immunizing the animals from which this RNA-immuno-carrier (RNA-I-C) was taken. The following investigations were undertaken to ascertain whether an RNA-I-C extracted from the serum of immunized animals of one species was able to induce antibody production in animals of a different species.

Young male rabbits were immunized by 6-8 intravenous injections of red blood cells (RBC) of rat or guinea-pig. The RNA-I-C extracted<sup>4</sup> from sera of rabbits immunized with guinea-pig RBC was introduced into normal rats; normal guinea-pigs were treated with RNA-I-C obtained from sera of rabbits immunized with rat RBC. The amount of RNA introduced in each animal of both groups, by a single intracardiac injection, was 0.28 mg/100 g

Table 1. IMMUNE RESPONSE OF RATS TREATED WITH RNA FROM ANTI-GUINEA-PIG RBC HYPERIMMUNE RABBIT SERA AND OF GUINEA-PIGS TREATED WITH RNA FROM ANTI-RAT RBC HYPERIMMUNE RABBIT SERA

	Guinea-pig RBC		Rat RBC	
	Rats treated with anti-guinea-pig RBC RNA	hemagglutination hemolysis	Guinea-pigs treated with anti-rat RBC RNA	hemagglutination hemolysis
Controls	0	0	0	0

48 h	1:320	1:160	1:320	1:80
72 h	1:80	1:80	1:40	1:20
96 h	neg.*	neg.	neg.	neg.

\* Negative is less than 10.

Fig. 1. Spectrophotometric behaviour of rat RBC or guinea-pig RBC hemolysis by: A, normal rat serum; B, normal guinea-pig serum; C, serum from rat 48 h after injection of anti-guinea-pig RBC RNA; D, serum from guinea-pig 48 h after injection of anti-rat RBC RNA

Fig. 2. Immunofluorescence test: guinea-pig RBC incubated at 37°C with serum (1:10) from rat 48 h after injection of RNA-I-C from rabbit anti-guinea-pig RBC sera, and then incubated with fluorescent anti-rat globulins

body-weight. At intervals of 24, 48, 72 and 96 h after RNA injection, blood samples were collected and the sera were subjected to haemagglutination tests and macroscopic and spectrophotometric<sup>4</sup> hemolysis tests.

The results of haemagglutinations and hemolysis are summarized in Table 1. The kinetic behaviour of hemolysis observed spectrophotometrically is shown in Fig. 1. The antigen-antibody reaction was also shown by the indirect immunofluorescent technique (Fig. 2). Check tests of RNA preparations were made by spectrophotometry in ultra-violet light.

The data confirm the possibility of eliciting an immune response by RNA-I-C extracted from the serum of immunized animals of a different species.

This investigation was supported by grants from C.N.R., Rome, and from the Ministero della Pubblica Istruzione, Italy.

## HISTOLOGY

Cyclic and Experimentally-induced Changes in the Histology of the Adrenal Gland in *Rana temporaria*

THE anuran adrenal gland consists of tissue strands in which the interrenal and chromaffin cells are intermingled. In some species a third cell type (summer- or Stilling-cell) has been described which has an eccentrically placed nucleus and cytoplasmic granules which are eosinophilic and stain metachromatically with basic dyes like toluidine blue. In *Rana temporaria* chromotropic cells are also present but differ from the foregoing in histological appearance; moreover, the cytoplasmic granules are not eosinophilic.

With the annual variation in environmental factors and the considerable seasonal changes in metabolic state, it might be expected that, in *R. temporaria*, the histological appearance of the adrenal gland might also vary throughout the year. The work recorded here is based on animals caught in the open during February 1962–January 1963. Five adult frogs were collected and killed every two weeks throughout this period. Adrenals were rapidly extirpated and fixed in Helly's fluid. Paraffin sections of 7  $\mu$  were stained with hæmatoxylin–eosin and alcian blue.

Cytologically two quite different cortical cells could be distinguished: (1) Cells with a compact cytoplasm containing few small vacuoles. The large nucleus was round or oval in outline with 1 or 2 clearly defined nucleoli ('compact cells'). (2) Cells with a highly vacuolated cytoplasm and an irregular crenated nucleus in which the nucleolus was difficult to distinguish ('clear cells'). Both cell types, and in addition several intermediate forms, were present at all periods of the year. The clear cells were always situated in the strands of the central part of the adrenal whereas the compact cells were present in the peripheral strands.

The cytological variations during the year were found to be in accordance with those reported by Fowler<sup>1</sup>, who stated that in spring and summer compact cells were more numerous than during the winter period. This author did not, however, mention changes in the general histological appearance of the gland. In the present material, in addition to strands in which each cell fits closely with its neighbours we frequently found strands in which cavities were present (Fig. 1). These cavities varied in size and were surrounded by cortical cells. The cavities were found at all times of the year, but were most numerous in April and August–September. In those parts of the gland where cavities were present, most of the chromotropic cells were situated within the cavities and not scattered among the cortical tissue. Sometimes the cavities were follicle-like, that is, surrounded by a single layer of cortical cells and mostly contained a colloid-like substance. Bulliard *et al.*<sup>2</sup> and Maillet<sup>3</sup> observed cortical cavities in the adrenal of *Rana esculenta* after treatment with adrenocorticotrophic hormone. The same were also described by Olivereau<sup>4</sup> in the eel after treatment with metopirone and adrenocorticotrophic hormone. It seems therefore not unlikely that the above cavities in the adrenal of *R. temporaria* reflect an active phase of the gland.

Since aldosterone has been reported in high concentration in Amphibia<sup>5,6</sup> a second investigation was undertaken to determine the effects of exogenously administered aldosterone, a known aldosterone antagonist. Moreover, the effect of metopirone, an inhibitor of the 11 $\beta$ -hydroxylation in the synthesis of corticoids, was also investigated.

After oral administration of 5 mg aldosterone/day during 18 days, the histological alterations pointed to an increased activity of the cortical tissue as a whole. As compared with the controls, all cortical cells of the aldosterone-treated animals showed a compact cytoplasm containing large

Fig. 1. Normal adrenal gland of *Rana temporaria* in April ( $\times$  c. 170)

Fig. 2. Adrenal gland of *Rana temporaria* after treatment with aldosterone in September ( $\times$  c. 170)

vacuoles which were quite different from those found in the compact cells already described here (Fig. 2). The nuclei were large and round in outline with 1 or 2 clearly defined nucleoli. Moreover, the cortical tissue showed an increased mitotic activity and the number of cavities was much higher than in control animals. The fact that these alterations occurred in the peripheral as well as the central part of the cortical tissue suggests that the aforementioned cytological differences between the cells of these two parts of the gland do not represent a functional zonation as can be seen in the mammalian cortex, but rather reflect a difference in activity of both kinds of cells.

Administration of 5 mg metopirone/day during 18 days resulted only in a small increase in mitotic activity of the cortical tissue. According to Olivereau<sup>4</sup> the effect of metopirone in the eel is maximal at the fourth day and thereafter diminishes rapidly in spite of prolonged treatment, even with high doses. It is therefore not impossible that the absence of marked changes after administration of metopirone can be explained by the long duration of the experiment.

## HISTOCHEMISTRY

## Effect of Denervation on the Lactate Dehydrogenase Isozymes of Skeletal Muscle

THE lactate dehydrogenase (LDH) isozyme pattern of many mammalian tissues has been shown to change with development<sup>1,2</sup>. Persistence of the foetal LDH pattern in skeletal muscle has been noted in chickens with hereditary muscular dystrophy<sup>3</sup> and in children with myopathy<sup>4</sup>. In the work recorded here an adult skeletal muscle was denervated in order to ascertain the effect of an acquired lesion on the LDH isozyme pattern.

The soleus muscle of an adult guinea-pig was unilaterally denervated by severing the sciatic nerve at the trochanteric level under general anaesthesia. A portion of nerve 1.5 cm long was removed. The animal was then permitted free movement in its cage and killed after 11 weeks. The soleus muscles from both hind-legs were excised, homogenized, submitted to starch-gel electrophoresis, and incubated to demonstrate LDH activity, according to the methods described previously<sup>5</sup>. LDH isozyme patterns of soleus muscles from new-born and normal adult guinea-pigs were prepared in the same manner. The LDH activities of all extracts were measured in a spectrophotometer and equalized at 30,000 units/ml. by dilution before application to the gel.

Predominance of the faster-moving LDH isozymes (LDH 1 and LDH 2) was found to characterize normal adult guinea-pig soleus<sup>6</sup> (Fig. 1C). The pattern of new-born soleus differed from that of the normal adult (Fig. 1B). It showed less activity of the fast-moving isozymes and greater activity of the slow-moving isozymes. The pattern of the denervated soleus also differed from that of the normal adult and resembled the pattern of the new-born (Fig. 1A). The soleus from the unoperated side of the denervated animal had an isozyme pattern identical to that of normal adult soleus.

Microscopic examination of the denervated soleus revealed only slight infiltration of connective tissue in addition to neurogenic atrophy of muscle fibres.

These results were confirmed with three adult guinea-pigs and with new-born guinea-pigs from three different litters. The observations are in accord with a recent chemical analysis of the forms of LDH in rabbit soleus by Dawson *et al.*<sup>7</sup>, who found that 'H-LDH' (which predominates in the fast-moving isozymes) increases more rapidly in the first several weeks of life than 'M-LDH' (which predominates in the slow-moving isozymes). Denervation

was found by these workers to produce greater loss of the H type than of the M.

The work recorded here indicates that experimental denervation of muscle may cause reversion to the immature LDH isozyme pattern. Not only does the intensity of the fast-moving isozymes decrease in the reversion of the guinea-pig soleus pattern but also the intensity of the slow-moving isozymes increases.

Resemblance to the immature LDH isozyme pattern is, therefore, a non-specific effect of either myopathic or neurogenic change in skeletal muscle and occurs in hereditary and acquired conditions.

## RADIOBIOLOGY

Retention of <sup>90</sup>Sr in Lactating Rats

IN previous investigations we were able to demonstrate that elimination of <sup>90</sup>Sr is enhanced in lactating rats<sup>1-4</sup>. Similar findings were reported by other investigators under various experimental arrangements and with various experimental animals<sup>5-10</sup>. To gain more quantitative information on Sr-metabolism in the course of lactation the following experiment has been performed.

Experimental animals were 32 albino rats of the 'Heiligenberg' strain, 15 weeks of age. 29 were dams carrying litters, the mean number of young being 9-10. Three virgin rats served as controls. Each rat received an intravenous injection of 2  $\mu$ c. of <sup>90</sup>Sr-<sup>90</sup>Y chloride in physiological saline and was killed 48 h thereafter. Time of injection varied with experimental groups so that 48-h retention could be evaluated for the end of gestation, the beginning of lactation and the end of lactation. Femora of dams and total litters were ashed dry. Radioactivities of samples of the ash from each femur were measured, and means were calculated for the litter. The experimental arrangement and results are recorded in Table 1.

As can be seen, ash-weights were elevated with respect to controls at the end of gestation and at the beginning of lactation. At the end of lactation they were lowered. Radioactivities of the femora were lower with all dams, the difference between groups 2 and 3 not being significant ( $P > 0.05$ ). In an earlier experiment<sup>2</sup>, different retentions of injected <sup>90</sup>Sr, compared with virgin controls, could not be established. With the present arrangement retention at the end of gestation was significantly lower. Diminution of radioactivity in the femora at days 15-17 post partum was highly significant. Radioactivities of the juveniles were roughly doubled for days 3-5 post partum compared to days 17-19 of gestation, and then once more for days 15-17 post partum. Therefore, participation of the litter on a dose of <sup>90</sup>Sr injected during lactation was growing continuously.

An approximation to the amount retained by the whole animal can be calculated from the figure derived from the femora by multiplication by a factor of 20. Retentions calculated for groups 1-4 are 51, 36, 42 and 17 per cent of the injected dose, respectively. Radioactivities retained in the biological system comprising mother and litter 48 h

Fig. 1. Photograph of a starch gel showing electrophoretic patterns of guinea-pig muscles. The LDH activity of each extract was adjusted to 30,000 units/ml. before application to gel. Arrow indicates origin: LDH isozymes are numbered from anode. A, adult soleus denervated 11 weeks; B, new-born soleus; C, normal adult soleus. Note predominance of fast-moving isozymes in normal adult soleus. In denervated soleus, the fast-moving isozymes are decreased in intensity, the slow-moving isozymes are increased, and the pattern resembles that of the new-born

Table 1. 48-h  $^{86}\text{Sr}$  RETENTION AND ASH-WEIGHT OF FEMORA, AT VARIOUS STAGES OF GESTATION AND LACTATION

Group	No. rats	Mean No. * young/litter	Time of retention of the isotope †	Mean ash-weight ‡ per femur (mg)	Mean radioactivity ‡ per femur (% of injected dose)	Mean radioactivity per liter (% of injected dose)
1 Virgin controls	3	—	—	213 ± 24	2.55 ± 0.08	—
2 Dams	9	10	17–19 of gestation	242 ± 12	1.84 ± 0.12	15.07
3 Dams	12	10	3–5 post partum	244 ± 11	2.10 ± 0.14	30.78
4 Dams	8	9	15–17 post partum	190 ± 8	0.84 ± 0.43	66.13

\* Or embryos in group 2. † From injection of the isotope to time of killing. ‡ Means with single standard deviations of the means ( $s_x$ )

after injection are therefore 51, 72 and 83 per cent of the injected dose for experimental groups 2–4. This indicates that at the end of gestation the retention of this system is roughly the same as that of virgin controls and is steadily elevated during lactation in contrast to the retention in the femora of dams. It is not clear, from the present experiment, whether this is accompanied by lowering of the faecal and urinary excretion of the mineral by the dams or the young or both. It may be mentioned, however, that Lenkeit<sup>6</sup> reported, in lactating sows, a considerable decrease of faecal and urinary excretion of Ca and a negative balance of Ca due to elevated secretion with milk.

### Absorption and Retention of Ingested Strontium and Calcium in Beagles as a Function of Age

INVESTIGATIONS of the metabolism of strontium and calcium in various species have shown that the two elements, though qualitatively similar, have distinct quantitative differences. The differential movement of strontium and calcium across physiological barriers is expressed by the term 'Strontium-Calcium Observed Ratio' (*OR*) and is given by:

$$OR \text{ sample-precursor} = \frac{\text{Sr/Ca sample}}{\text{Sr/Ca precursor}}$$

The  $OR_{\text{bone-diet}}$  values for laboratory and domestic animals (cow, goat, sheep and rat) under usual dietary conditions range from 0.2 to 0.5 with most of the values at about 0.25 (refs. 1 and 2). Limited data for man suggest a range of 0.25–0.5 under different dietary and environmental conditions. Unfortunately, few data have been reported for the dog.

In the present work, the absorption and retention of strontium and calcium were determined in beagles of different ages after ingestion of a single meal containing known amounts of  $^{86}\text{Sr}$  and  $^{45}\text{Ca}$ . The value of the  $OR_{\text{bone-diet}}$  in a given species can be used to estimate the deposition and retention of strontium. Thus, at a continuous or chronic intake of  $^{86}\text{Sr}$  per g of dietary calcium the skeleton would be uniformly labelled, and the body burden estimated as follows:  $\mu\text{c.}^{86}\text{Sr/g Ca}_{\text{diet}} \times OR_{\text{bone-diet}} \times \text{total Ca in species} = \mu\text{c.}^{86}\text{Sr in skeleton}$ . The data obtained on the differential uptake of  $^{86}\text{Sr}$  and  $^{45}\text{Ca}$  (*OR*) in the dog were used as a guide in the preparation of diets containing  $^{86}\text{Sr}$  to yield predictable body burdens

under a continuous dietary regimen. Such an experiment is in progress at the University of California at Davis, to investigate the long-term effects of chronic ingestion of  $^{86}\text{Sr}$  at given  $^{86}\text{Sr}/\text{Ca}$  ratios<sup>3</sup>.

Sixteen pure-bred beagles were used, ranging from 48 to 2,060 days of age. Eleven dogs were maintained on a compounded 1 per cent calcium diet (Ca/P weight ratio of 1.5) for several months before the experiment and in most cases from birth. Five dogs were maintained on a 2 per cent calcium diet (Ca/P weight ratio 1.5) for a 30-day equilibration period before the experiment. In both cases, the diets were composed of 60 per cent dry kibbled ration plus 20 per cent meat and 20 per cent (by weight) water, and required vitamin supplements. The dietary calcium was essentially all in the dry ration and was controlled within reasonable limits by selection of natural materials only. The calcium content of the two dry rations was 1.7 and 3.3 per cent by weight, respectively.

High specific activity  $^{45}\text{Ca}$  was obtained from Oak Ridge National Laboratory, Tennessee. It decays with a 4.7-day half-life and emits  $\gamma$ -rays at 1.29, 0.81 and 0.50 MeV. Carrier-free  $^{86}\text{Sr}$  (65 days half-life) emits a 0.513-MeV  $\gamma$ -ray. It was obtained from Nuclear Science and Engineering Corp., Pittsburgh, Pa. The energies of the  $\gamma$ -rays differ sufficiently to permit good pulse-height differentiation. The  $^{45}\text{Ca}$  contribution to the 0.513-MeV  $^{86}\text{Sr}$  photo peak can be corrected by comparison of the  $\gamma$ -ray spectra of the two radionuclides in the calibration standards. The  $^{86}\text{Sr}$  estimate for each dog was reduced by that fraction of the standard  $^{45}\text{Ca}$  spectrum detected at the  $^{86}\text{Sr}$  window. A single channel analyser was adjusted to record the  $\gamma$ -ray pulses within a 0.120-MeV energy band centred over either the 0.513-MeV  $^{86}\text{Sr}$  or the 1.29-MeV  $^{45}\text{Ca}$  photo peaks.

Standards of each radionuclide were prepared at the time of feeding by placing 200  $\mu\text{c.}^{86}\text{Sr}$  and/or 500  $\mu\text{c.}^{45}\text{Ca}$  in a 2-l. plastic bottle the approximate size of the smallest test animal. Two annular paraffin cylinders into which these standards could be placed were also prepared to approximate to the geometry of medium and larger-sized dogs.

The test meals were prepared by using aliquots of the radionuclides, as used in the standards, which were added to the mixture of meat and water, followed by thorough blending with the dry ration. To ensure complete consumption, the food was offered after a short fast and, in the case of the very young animals, in two divided portions a few hours apart.

The first  $\gamma$ -ray counts were made within 1 h after ingestion. The dog measurements were compared to the standards at each counting time and the data expressed as percentage of the initial dose. This eliminated any necessity for corrections for the physical decay of the radionuclides.

The single-channel analyser used for these investigations was fed by a 5 × 5 cm Na I (Tl) scintillation crystal mounted in a shield constructed of 5 × 10 × 20 cm lead bricks. The detector, surrounded by 10 cm of lead, faced out into an open lead-walled 'horn' the wide end of which was the same size as the lateral face of a dog restraint box made of wood and 'Lucite'. A constant distance (63 cm) was maintained between the midline of the dog (unanaesthetized), and/or standards, and the crystal face.

Fig. 1. Biological retention curves of  $^{85}\text{Sr}$  and  $^{47}\text{Ca}$ , percentage of administered dose versus age averaged, 3-9 days after ingestion, 1 per cent calcium diet

Fig. 1 shows the biological retention curves of  $^{85}\text{Sr}$  and  $^{47}\text{Ca}$  expressed as the percentage of administered dose versus age averaged at 3-9 days after ingestion of the 1 per cent stable calcium diet. The retention curves indicate that strontium and calcium are absorbed in a qualitatively similar manner. The absorption and retention of administered  $^{85}\text{Sr}$  and  $^{47}\text{Ca}$  decrease rapidly with increasing age of the animal. After 250 days there is little effect of age on the percentage retention of the two radionuclides, which average about 5 per cent for calcium and 2 per cent for strontium. The highest absorption was observed in the youngest dog (48 days old at feeding) at about 44 per cent for calcium and 19 per cent for strontium.

Fig. 2 shows the values of the observed ratios ( $OR$ ) expressed as the ratio of  $^{85}\text{Sr}/^{47}\text{Ca}$  in the 1 per cent stable calcium diet. A line shows the average  $OR$  value of 0.45 for all ages. Under the ages and conditions of this experiment, no effect of age on the  $OR$  was evident, despite the age-dependency of the uptake of these elements.

The effect of increased dietary calcium (2 per cent) on the absorption of  $^{85}\text{Sr}$  and  $^{47}\text{Ca}$  in five beagles is shown in Table 1, and the data are compared with those obtained

Fig. 2. Observed ratios, body to diet, in beagles at various ages, 1 per cent calcium diet

Average			0.45			0.53

\*  $OR = \frac{\text{Sr/Ca body}}{\text{Sr/Ca diet}}$

from the 1 per cent calcium diet. The average percentage retention (3-9 days after ingestion) for both  $^{85}\text{Sr}$  and  $^{47}\text{Ca}$  is significantly reduced in beagles on the 2 per cent calcium diet. A two-fold increase in the calcium ingestion resulted in a nearly two-fold decrease in the absorption of  $^{85}\text{Sr}$  and  $^{47}\text{Ca}$ . The  $OR$  body-diet values appear to be somewhat higher at the 2 per cent dietary calcium level; that is, the average  $OR$  is 0.53 compared with 0.45. The decreased absorption and retention of  $^{85}\text{Sr}$  and  $^{47}\text{Ca}$  observed here confirm the observations made by Wasserman *et al.*<sup>4</sup> in growing rats over a four-fold variation in dietary calcium with the Ca/P maintained at a constant ratio. No significant change in the value of the  $OR$  was observed by these investigators; the difference seen in the present investigation could be attributed to the small number of dogs, to age distribution, or to possible species differences.

The differential metabolism of strontium and calcium in beagle dogs has been shown to be comparable in magnitude to that in other mammalian species. The value of the observed ratio ( $OR$ ) in beagles in equilibrium with the dietary calcium and phosphorus environment varies between 0.3 and 0.5 (average 0.45) at widely different ages. A preliminary report by Stover, Goldman and Andersen<sup>5</sup>, based on a single dog, indicated that the value of the  $OR$  might approximate to unity under conditions of continuous ingestion. It now appears that the reported  $^{90}\text{Sr}$  to calcium ratio in the diet was in error by a factor of about 2. Only the diet data appear erroneous, for the skeletal data in the original report have been verified. Further work by Della Rosa<sup>6</sup> under conditions of continuous feeding of  $^{90}\text{Sr}$  at constant  $^{90}\text{Sr}/\text{Ca}$  ratio confirms the findings of the single double double tracer feeding reported here.

## BIOLOGY

Locomotion in the Australian Marsupial  
*Antechinomys*

THE so-called 'jerboa marsupial' of Australia (*Antechinomys*) is widely held to be bipedal and convergent on bipedal saltatory murids or jumping mice (*Notomys*); various species of these occur in identical localities with *Antechinomys* in rather arid parts of Australia from Western Australia to Queensland. This interpretation of locomotion in *Antechinomys* is to be found in most general works on Australian marsupials and, as an example of evolutionary convergence, in zoological text-books<sup>1-4</sup>.

Fig. 1

During the past year I have kept four *Antechinomys spenceri* and one *Notomys richardsoni* in captivity; they are often allowed free to run in my home. Electronic-flash photographs and ciné-film have been taken of them, and these reveal that *Antechinomys* is consistently quadrupedal. Fig. 1 illustrates typical stages in the gallop. The sequence illustrated is made up from selected electronic-flash photographs arranged in the order shown to be natural in cinematographic film taken under similar conditions. This sequence takes from 0.2 to 0.25 sec to complete.

The jumping-mouse, *Notomys richardsoni*, photographed under these conditions is bipedal and saltatory.

## Mechanism of Anaphylactic Death in the Mouse

GUINEA-PIG anaphylaxis has for many years been considered the classical example of anaphylaxis. In this animal, challenged intravenously, anaphylactic shock is believed to be due to liberation of histamine with subsequent contraction of smooth muscle. Contraction of the bronchial musculature completely shuts off the alveoli and prevents exhalation of air, and the animals die of asphyxia. If the shocking dose of antigen is given by the intraperitoneal or subcutaneous route, death in many cases is not due to asphyxia, but occurs slowly (protracted anaphylaxis), and cannot be attributed to respiratory failure<sup>1,2</sup>. In other animals, anaphylactic death has also been associated with a 'selectively' shocked organ. Thus,

in the rabbit, the constriction of pulmonary arterioles and extreme dilation of the right heart lead to acute fatal heart failure. In the dog, marked liver congestion seems to be responsible for death<sup>3</sup>.

In the mouse, anaphylactic shock is always accompanied by respiratory distress, cyanosis and some degree of oedema. Symptoms associated with smooth muscle contraction are evident, but not striking. Other characteristic symptoms are marked lack of activity and uncoordinated motor response. A mouse which has just died of anaphylaxis has collapsed and unobstructed lungs, a heart that is still beating and an uncongested liver. All the rest of the abdominal organs appear normal, except for a generalized injected and oedematous appearance of

the intestines and stomach. Consequently, death of the mouse is not due to obstruction of the lungs or liver or to cardiac failure. The mouse undergoing anaphylaxis does show signs of respiratory distress and anoxia. Within 1 min after antigen injection an intense spasm of the arterioles and venules occurs followed within 5-20 min by a marked relaxation of these vessels and a fall in blood pressure. All the vessels become dilated with slow-moving blood<sup>4</sup>. In the experiments to be reported, mice undergoing anaphylaxis appeared to experience an actual loss in blood volume, and replacement of the blood volume protected them from anaphylactic death.

Experiments were conducted to explain the obvious respiratory distress always observed in mouse anaphylaxis. It is known that the capillaries become strikingly dilated and that circulation is retarded<sup>4</sup>. During anaphylaxis mice are extremely difficult to bleed; little blood can be obtained by cutting the tail veins and arteries or by puncturing the infra-orbital sinus. If the heart of a mouse which has just died of anaphylactic shock is cut open, little bleeding occurs. These observations suggested that a marked loss of effective blood volume has occurred or that dilation of vessels has produced circulatory collapse.

The following experiments were performed to determine the cause of this circulatory failure. Mice were immunized with 0.5 mg of egg albumen in incomplete Freund's adjuvant, and 21 days later the hematocrit values were

Table 1. HEMATOCRIT VALUE CHANGES DURING ACTIVELY INDUCED ANAPHYLAXIS

Mouse No.	Sensitized mice*		Normal mice*	
	Pre-challenge	Post-challenge	Pre-challenge	Post-challenge
1	49	72	51	50
2	45	60	44	45
3	52	70	49	47
4	45	65	46	46
5	52	74	49	46
6	50	73	49	49
7	47	64	48	46
8	48	65	46	46
9	51	67	51	50
10	47	69	51	49
Average	48.6	67.9	48.4	47.4

\* All sensitized mice eventually died of shock, while all the normal controls survived without symptoms of anaphylaxis.

determined for them and for normal controls before and after an intravenous challenge with 0.5 mg egg albumen. The post-challenge sample of blood in sensitized mice was taken when strong symptoms of anaphylaxis had developed. Control mice were bled 5 min after challenge. The results given in Table 1 indicate that, in all cases where anaphylaxis occurred, the haematocrit value was increased markedly. From these values, it could be calculated that 20–30 per cent of the blood volume had disappeared from the circulation within 5 min after challenge. No such effect was observed in the normal control animals. These observations indicated that fatal anaphylaxis might be the result of insufficient oxygenation of the tissues due to severe loss of blood volume and to dilatation of the capillary bed. The respiratory distress, oedema and cyanosis observed are thus explained. If this is indeed the main cause of death, it should be possible to save these mice by merely replacing the blood volume.

Table 2. PROTECTIVE EFFECT OF BLOOD VOLUME REPLACEMENT IN MOUSE ANAPHYLAXIS\*

Fluid used	No. of injections	Vol. per injection (ml.)	Results survivors/total
6 per cent dextran	2 to 3	0.3 to 0.5	9/9
Physiological saline	2 to 3	0.3 to 0.5	9/10
Untreated controls	—	—	2/10

\* Sensitized mice were challenged intravenously and as soon as strong symptoms of anaphylaxis appeared treatment was initiated. An intravenous injection of 0.5 ml. plasma volume extender was first given. The animals were observed and, if severe shock was again obvious, another intravenous injection of 0.3–0.5 ml. was given. In a few cases, a third injection was needed. Treatments were stopped 1 h after the shocking dose.

Mice sensitized as in the previous experiment were similarly challenged, and, as soon as anaphylactic symptoms appeared, intravenous treatment with either 6 per cent dextran solution or with plain physiological saline was begun. Complete and dramatic protection of mice resulted with as few as 1–3 injections of 0.3–0.5 ml. of either dextran solution or physiological saline (Table 2). In many animals anaphylactic shock had progressed so far as to seem irreversible. At this point, injection of 0.5 ml. of 6 per cent dextran solution or physiological saline restored life to many of these mice. The only animals which were not protected were those in which the veins of the tail were extremely difficult to inject and replacement therapy was impossible. Mice received no further treatment 1 h after challenge. Deaths seldom occurred after this time, and the following day these mice seemed normal. Similar experiments in which the mice were passively sensitized gave comparable results.

These findings indicate that the mouse undergoing anaphylactic shock dies of circulatory failure due mainly to loss of effective blood volume. This effective loss of volume must be due not only to dilation of blood vessels but also to an increased permeability of the capillaries which allows fluids to escape. This would explain the oedema and haemoconcentration observed. The anoxic condition may be due to lack of circulation of blood and insufficient oxygen transport to the tissues, which in turn would explain the cyanosis observed. The oedema noticed in the peritoneal cavity is probably due to increased permeability of vessel walls. Other symptoms associated with smooth muscle contraction (ruffled hair, defaecation and urination) are also observed and are most likely due to release of substances, such as serotonin or histamine, from the anaphylactically shocked tissues.

## A Cytoplasmic Organelle associated with the Cell Walls of *Chara* and *Nitella*

MATURE internodal cells of the algae *Chara* and *Nitella* are several centimetres long, and develop from meristematic cells about 20  $\mu$  across. In an investigation of the fine structure of developing internodal cells in *Chara* and *Nitella*, an unusual organelle has been seen in the cytoplasm. In young internodal cells the organelle had a superficial resemblance to a mitochondrion, but a mitochondrion is always surrounded by a double membrane, whereas the organelle had a single outer membrane about 75  $\text{\AA}$  thick which resembled the 'unit' membrane of Robertson<sup>1</sup>. In immature cells the organelle membrane appeared to be discontinuous on its cell-wall side, leaving small gaps through which there was contact between the inner structure of the organelle and the cell wall (Fig. 1). In developing cells the organelles were elongated in the direction of cell growth (Figs. 2 and 3) and the membrane surrounding the organelle appeared to be continuous with the cell membrane, of which it may be an extension.

The organelle contained a system of interconnected tubules with diameters varying from 200  $\text{\AA}$  at their narrowest to 500  $\text{\AA}$  at their widest parts. The walls of the tubules were single membranes like those of the cristae in the mitochondria, but a granular material within the tubules made them appear dense, whereas the mito-

Fig. 1. Part of a young internodal cell in *Chara*. There is close contact between the organelles and the cell wall through gaps in the cell membrane. The single membrane of the organelle passes near the double membranes of chloroplasts. ( $\times 21,000$ )

Fig. 2. This organelle is elongated in the direction of the long axis of a developing internodal cell. The membrane of the organelle is continuous with the cell membrane, and the tubules within the organelle are in very close contact with the cell wall. ( $\times 42,000$ )

Fig. 3. At a later stage of cell development the membrane of the organelle appears to be part of the cell membrane. The structure of the tubules can be compared with that of the cristae within the mitochondrion. ( $\times 30,000$ ). o, organelle; t, tubule; m, mitochondrion; c, chloroplast; cm, cell membrane; cw, cell wall. Scale represents one micron

chondrial cristae appeared to be empty (Fig. 3). When differentiating cells were plasmolysed during preparation for the electron microscope, some of the tubules remained attached to the cell wall. The organelles were not seen in the segment cell or in mature internodal cells, and Green<sup>2</sup> has shown that the cell walls are isotropic at both these stages of development. The organelles were seen in developing internodal cells, which have birefringent walls<sup>2</sup>.

The close association between the cell wall and this organelle suggests that it may be involved in the organization of cell wall structure or the synthesis of cell wall material. Frei and Preston<sup>3</sup> have shown that microfibrils in the cell walls of a number of species of algae are arranged in a regular pattern, and that the angles between them are similar. Preston<sup>4</sup> proposed a structure capable of synthesizing cell wall material, which consisted of three layers of spheres, each about 500 Å in diameter and arranged in cubic close packing: such a structure could synthesize microfibrils at the angles which he observed. The organelle described here does not have the structure proposed by Preston, but Green<sup>2</sup> has shown that the microfibrils in the walls of internodal cells in *Nitella* are arranged transversely.

Ledbetter and Porter<sup>5</sup> fixed root tips of higher plants in glutaraldehyde and found tubules in the cytoplasm which, they suggested, were associated with cell wall structure. The organelles observed in *Chara* and *Nitella* were not so well preserved by fixation in osmium tetroxide or potassium permanganate as they were by fixation in glutaraldehyde. Glauert and Hopwood<sup>6</sup> saw membranous structures near the growing cross walls of bacteria, which they also interpreted as organelles responsible for cell wall synthesis.

### An Unusual Organelle in the Peripheral Cytoplasm of *Chara* Cells

DURING the course of an investigation of the fine structure of the development of laterals of limited growth of *Chara*, unusual structures were observed at the surface of some of the cells (Fig. 1). They consisted of an invagination of the plasmalemma, approximately ovoid in shape, containing a knot of anastomosing tubules. Each tubule, when cut transversely, showed a circular outline, 200–500 Å in diameter, bounded by a single unit membrane the same thickness as the plasmalemma. The organelles were present in the cylindrical cells of well-developed laterals, being confined to the cytoplasm adjacent to the outer walls, where they lay next to the layer of chloroplasts found in this region. Mitochondria also occurred in this position but, while superficially resembling the organelles, they could be distinguished because of their double outer membrane. The organelles were not observed in meristematic cells of young lateral branches.

In some cases the tubules were observed to be extensions of the plasmalemma. The organelles described here could therefore be interpreted as localized modifications of the surface membrane, the increased surface area probably being associated with some specific enzymatic activity.

Since the organelles are situated in contact with the developing cell wall it seems probable that they are sites of synthesis and/or organization of wall material. Frei

and Preston<sup>1</sup> put forward the hypothesis that synthesis and organization of cellulose fibrils are associated with granular regions observed on the interior surfaces of the walls of *Cladophora* and *Chaetomorpha*, and Preston<sup>2</sup> postulated a three-dimensional model at or near the cell surface to account for this synthesis. On the other hand, these organelles might be involved in the formation of other extra-cellular materials such as non-cellulosic wall substances.

Although it is unlikely that the invagination of the plasmalemma reported here is some stage in pinocytotic activity, the increase in surface area of the outer membrane in these organelles might be related to the uptake of substances into the cells.

I thank Prof. P. F. Wareing for his advice and P. Henley for assistance.

### Heterocyst Germination under Defined Conditions

ONLY on rare occasions have heterocysts of blue-green algae been seen to germinate. The observations of a number of investigators have supported various suggestions as to non-reproductive functions of these cells. However, no definitive elucidation of their function has yet been presented<sup>1</sup>. Indicative of the apparent infrequency of heterocyst germination under natural conditions is Fritsch's<sup>2</sup> comment that in a six-month survey of algal material from all over the world, he had observed no single case of a germinating heterocyst. If conditions could be established which would invariably result in germination of these cells, these conditions could then suggest natural environments in which heterocyst germination might be successfully sought.

A clonal, axenic culture of a blue-green alga identified as *Anabaena cylindrica* Lemm. was derived from culture B381 *Anabaena* sp. of the Indiana University algal culture collection<sup>3</sup>.

In accordance with the results of Fogg<sup>4</sup> and Pandey and Mitra<sup>5</sup>, heterocyst formation in this alga was found

Figs. 1a and b. Pairs of germinating heterocysts (GH) from a Petri dish culture

to be inhibited by ammonium ions. This finding led to a test of the ability of ammonium to induce heterocysts to germinate.

Medium C of Kratz and Myers<sup>6</sup> was modified by the substitution of  $\text{NH}_4\text{Cl}$ , at 4 mmoles/l., for  $\text{KNO}_3$ , and by the replacement of  $\text{Ca}(\text{NO}_3)_2$  by  $\text{CaCl}_2$ . Glucose was added at a concentration of 50 mmoles/l. To prevent germination products from floating apart, the medium was solidified with 0.92 per cent agar. Use of highly purified agar<sup>7</sup> was essential. Cooled but liquid double-concentration agar, autoclaved in 'Pyrex'-redistilled water, was combined with an equal volume of a filter-sterilized double-concentration solution of the remaining constituents of the medium. Two-ml. aliquots of medium were pipetted into disposable sterile Petri dishes (35 mm  $\times$  10 mm) (Falcon Plastics), and let set for at least several hours. Algal inocula were grown on a variant of medium C of Kratz and Myers<sup>6</sup> as described elsewhere<sup>8</sup>. A very small amount of inoculum-suspension was streaked on the agar. The cultures were exposed to continuous illumination from General Electric cool-white fluorescent lamps. Light intensity, as measured with a Photovolt Corporation model 200A photometer, was 175 ft.-candles. Temperature was maintained at 23.5° C. The cultures were examined 9–13 days later. Inhibition of heterocyst formation ceased soon after the thirteenth day. Assays of heterocyst germination were made at 400 times magnification using a 40 times magnification long working distance objective lens (Cooke—A.E.I.). Cover slips were never used, so that the observations themselves did not result in mechanical opening of heterocysts.

Consistently, from 3 to c. 10 per cent of the identifiable heterocysts observed were found to be germinating or to have germinated. That is, the thick heterocyst coats had broken open, and in the great majority of cases a multicellular germling was observed extending through the opening in the coat. Figs. 1a and b show pairs of germinating heterocysts encountered in a representative culture. In the absence of glucose and  $\text{NH}_4\text{Cl}$ , germination was rarely observed.

It cannot be stated that germination is a common fate of heterocysts until evidence to this effect is found

in natural environments. There are several possible ways of explaining the fact that although very infrequently observed in Nature, heterocyst germination may be obtained under rather simple conditions in the laboratory. The identification of a germinated heterocyst as such can be difficult, particularly if germination has occurred in a liquid medium, where germling and heterocyst coat can become easily separated. According to Brand<sup>9</sup>, a discarded heterocyst coat soon becomes unrecognizable. Desikachary<sup>10</sup> states that discarded coats eventually dissolve. Geitler<sup>11</sup> has pointed out the ease of overlooking germination stages. Sites rich in ammonia might well be the best in which to start a search for evidence of abundant heterocyst germination under natural conditions.

It has been found<sup>3</sup> that phosphate-starvation stimulates sporulation of *A. cylindrica*, and that spores which develop under such conditions germinate on a phosphate-containing agar medium. Low-nitrogen media, on the other hand, stimulate heterocyst-formation, and an ammonium-containing medium leads to heterocyst germination. These results suggest that the spores of *A. cylindrica* may have become specialized for surviving periods of phosphate deficiency, and the heterocysts for surviving periods of nitrogen deficiency. Different germination requirements for two resting-cell types of the same organism should be useful for investigations of the comparative physiology of germination.

### Isolation of Salivation Factor from *Rhizoctonia leguminicola* on Red Clover Hay

IN 1959 O'Dell, Regan and Beach<sup>1</sup> in Missouri reported a new widespread toxicity problem associated with second-cutting red clover hay. Cattle and sheep which ate such hay slobbered excessively, went off feed, developed diarrhoea, bloat, stiff joints, and sometimes died. The toxic principle was organic in nature, slowly lost activity in solution and was soluble in water, ethyl alcohol and chloroform. Byers and Broquist<sup>2,3</sup>, investigating similar cases in Illinois, suggested that an alkaloid was involved, but did not identify the causal agent. Watson<sup>4</sup> and Guss<sup>5</sup> observed similar problems in dairy cattle consuming red clover hay.

Smalley *et al.*<sup>6</sup> and Crump *et al.*<sup>7</sup> investigated a similar disorder in ruminants in Wisconsin. They observed that samples of red clover forage associated with the excessive salivation in dairy cattle were infested with a dark-brown coloured fungus identified as *Rhizoctonia leguminicola* Gough and Elliott, the cause of the black patch disease of red clover. These authors concluded that the 'salivation factor' was contained in the mycelium of *R. leguminicola* and was not a product of red clover *per se*.

The objectives of the work recorded here were to purify the salivation factor, elucidate its chemical structure, and determine the effects of the purified toxin on animals.

*R. leguminicola* isolated from second-cutting red clover hay from Galesville, Wisconsin, was grown as still cultures on a medium containing 20 g soybean meal, 20 g dextrose, 5 g CaCO<sub>3</sub>, and 5 g corn steep liquor per litre distilled water. This medium<sup>8</sup> yielded consistent and reproducible production of the active principle. Optimum age for growth of the cultures was 30 days.

For bioassay of the salivation factor, guinea-pigs (200–300 g) were anaesthetized with medicinal grade ether, then stomach-fed 10 ml. of the test solution and placed in cages for observation. Every 15 or 20 min for the next 5–6 h each animal was rated for the degree of response to the feeding trial. Numerical ratings were assigned as follows: 1 = no response; 2 = slight salivation; 3 = extensive salivation, lacrimation and defaecation; 4 = severe depression, salivation, lacrimation, defaecation and dyspnoea; 5 = death. This rating provided a semiquantitative measure of the activity of the preparation tested.

For a typical purification run, about 100 cultures from 500-ml. Erlenmeyer flasks each containing 150 ml. of medium were used. The mycelial mats were removed, air dried (about 1 g dry wt./mat), ground to a fine powder in a Wiley mill, stirred with water (2 l./100 g dry wt.) at pH 6 for 2 h at 70° C and filtered. The filtrate was adjusted to pH 1 with hydrochloric acid and extracted three times with an equal volume of ether each time. The aqueous layer was then adjusted to pH about 10.5 with solid sodium carbonate and again extracted three times with an equal volume of chloroform each time. The active chloroform extract was evaporated to dryness, the residue redissolved in about 15–20 ml. of dilute hydrochloric acid and re-extracted three times with 15–20 ml. of ether. The aqueous fraction (about 20 ml.) was mixed with an equal volume of aqueous ammonium reineckate solution (saturated at 0° C), the mixture kept for 1 h at 0°, and the precipitate collected on a sintered glass filter and redissolved by washing with acetone through the filter. An equal volume of water was added to the acetone solution (15–20 ml.), and the acetone removed under vacuum. The aqueous solution was then made basic (pH 10) with sodium carbonate, extracted three times with an equal volume of chloroform each time, and the chloroform evaporated. The crude bases so obtained weighed about 80 mg.

This material was dissolved in 15 ml. of chloroform and chromatographed on 50 g of silicic acid (325 mesh) contained in a column (2 cm internal diam.). Successive passage through the column of 200 ml. chloroform, 200 ml. methanol and 200 ml. of 50 per cent aqueous methanol failed to elute the active material (as tested by spotting on filter paper and spraying with iodoplatinate reagent). The activity was then eluted with 0.01 N hydrochloric acid, the eluate (100 ml.) made basic with sodium carbonate (pH 10) and extracted with chloroform as before. Evaporation of the chloroform extract left a 20 mg residue which gave a rating of 3 when tested at a level of 1.4 mg/kg body wt.

The foregoing preparation was dissolved in 5 ml. of chloroform and the solution introduced into a chromatographic column which had been prepared by slurring 20 g of 'Florisil' in chloroform and pouring into a 1.5 cm internal diameter tube. Elution with 50 ml. of chloroform followed by 50 ml. of 25 per cent methanol in chloroform removed no active material. The iodoplatinate-positive material did not appear in the eluate until the column was developed with pure methanol. Evaporation of the active fractions left a residue weighing 4 mg. This was dissolved in 2 ml. water containing a trace of hydrochloric acid, and a saturated aqueous solution of picric acid was added drop by drop until no more precipitate formed. The product was collected and crystallized from 20 per cent ethanol. One recrystallization from the same solvent gave 2.8 mg of yellow needles, m.p. 178°–181°. The picrate was decomposed with excess hydrochloric acid, picric acid removed by extraction with ether, and the aqueous solution tested on guinea-pigs after neutralization. Ratings of 2 and 3 were obtained with doses corresponding to 0.17 and 0.29 mg of the picrate/kg body-wt., respectively.

The most highly purified material gave positive alkaloid tests (precipitates) with phosphotungstic acid, potassium bismuth iodide, and potassium mercuric iodide. At various stages of the purification the concentrates were examined by chromatography on Whatman No. 1 paper with the solvent system butanol:acetic acid:water (120:30:50 by vol.). The ascending technique was used. Under these conditions the most highly purified material gave only one spot at  $R_F$  0.35. The material gave an orange colour with Dragendorff's reagent, a grey colour with iodoplatinate and was negative to Ehrlich's reagent. With some of the less-highly purified fractions, faint ninhydrin positive spots were noted at  $R_F$  0.35 and 0.1.

The purified alkaloid obtained from the recrystallized picrate exhibited a weak band at 264 m $\mu$  and end absorption below 240 m $\mu$  when examined in aqueous solution containing excess hydrochloric acid.

The general chemical behaviour of the *R. leguminicola* toxin leaves little doubt that the substance is an alkaloid. Its physiological properties as an irritant are somewhat similar to those of physostigmine. However, physostigmine is distinctly different from the salivation factor chemically and at similar toxic doses on guinea-pigs caused severe griping and defaecation with only slight salivation. No signs of pulmonary involvement, lacrimation and prolonged salivation were apparent as seen with the salivation factor.

Cattle, swine, sheep, chickens, guinea-pigs, rats and mice have been investigated with respect to their response to the salivation factor. All were sensitive to the material, but ruminants seemed to be somewhat less reactive than other animals. Efforts to characterize the toxin are in progress.

This investigation was supported in part by U.S. Public Health Service research grants No. 00140 from the Division of Environmental Engineering and Food Protection and No. A1 04419 from the U.S. National Institute of Allergy and Infectious Diseases, and by the Research Committee of the Graduate School. We thank Prof. R. E.

Nichols for assistance in supplying animals and cage facilities and for his advice.

### Isolation of a Parasympathomimetic Alkaloid of Fungal Origin

SINCE 1947, reports have reached us of excessive salivation in ruminants after consuming certain forages. Frequently these forages were red clover hay, but other types of forages were involved. The cattle would consume from 1 to 3 feedings of such forage, salivate excessively, and then refuse further feed. The refusal of the cattle to consume 'slobber forage' represents an economic loss to the farmer, including a loss of milk production and the necessity of purchasing replacement forage.

Byers and Broquist<sup>1</sup> reported that slobbering in cattle and guinea-pigs could be also induced following the administration of a hot water extract of 'slobber forage'; certain properties of such extracts suggested that the salivation factor might be alkaloid in nature<sup>1,2</sup>. Smalley *et al.*<sup>3</sup> observed that all samples of 'slobber forage' were infested with a black fungus. They isolated the fungus in pure culture and identified it as *Rhizoctonia leguminicola*; guinea-pigs force-fed the mycelia salivated profusely. This report concerns the isolation of an alkaloid from this fungus having salivation factor activity, which thus appears to account for the early observations from this laboratory on 'slobber forages'.

*Rhizoctonia leguminicola* was obtained from Dr. J. W. Gerdemann of this University, who had isolated a pure culture of this fungus from red clover. The culture was maintained on potato-dextrose-agar slants and produced the salivation factor maximally when grown aerobically on a cold-water extract of second-cutting red clover hay. Medium was prepared by infusing 4 kg chopped hay with 20 l. cold water for 4 h and straining through cheesecloth. The medium was dispensed in 300-ml. quantities in 1-l. Roux bottles and autoclaved for 30 min at 120° C. The flasks were then inoculated from agar slants by the aseptic addition of *R. leguminicola* mycelium to the side of the glass bottles at the surface of the medium. The mould was grown in stationary culture at room temperature until the mycelial pad had covered the surface of the medium (generally about three weeks). Salivation factor activity was assayed qualitatively by injecting intraperitoneally guinea-pigs weighing 200–300 g with appropriate test materials and observing the degree of salivation at 15-min intervals. The degree of salivation was graded from 0 to 3; only sub-lethal doses were graded.

Approximately 2 kg of mycelia (wet wt.) was homogenized in a Waring blender with 95 per cent ethanol. The homogenate was filtered through Soxhlet extraction thimbles. The thimbles containing the homogenized mycelia were then placed in Soxhlet extractors and

extracted with the ethanolic filtrate for 48 h. The extract was then concentrated *in vacuo* to remove the ethanol and water added to a volume of 1 l. This solution, made slightly acidic (hydrochloric acid), was repeatedly extracted with CHCl<sub>3</sub> until fresh CHCl<sub>3</sub> extracts were colourless. The organic layer was discarded and the aqueous layer was then brought to pH 10 (powdered Na<sub>2</sub>CO<sub>3</sub>) and extracted with three volumes of CHCl<sub>3</sub>. The CHCl<sub>3</sub> fraction was retained, concentrated *in vacuo* to dryness, and the residue taken up in 100 ml. 0.01 N hydrochloric acid. The process of extracting the aqueous layer with CHCl<sub>3</sub> under acidic and then alkaline conditions was repeated. Following removal of the CHCl<sub>3</sub> from the latter step, the salivation factor concentrate was taken up in water and lyophilized, finally to yield 143 mg crude salivation factor which served as convenient source material for subsequent purification procedures.

When this material (50y) was chromatographed on paper in a butanol:acetic acid:water (4:1:1) system, one major and two minor components were found which stained pink following spraying with Dragendorff's reagent, a reagent diagnostic for alkaloids<sup>4</sup>. The major component ( $R_F = 0.25$ ) was accumulated by large-scale preparative paper chromatography and when eluted from the chromatogram elicited salivation factor activity.

Crude salivation factor was dissolved in dry CHCl<sub>3</sub> and hydrochloric acid gas passed through the solution. On standing overnight a reddish, semi-solid oil formed. Attempts were made to crystallize this material, thought to be salivation factor hydrochloride, from propanol-ethylacetate mixtures, but only amorphous precipitates were obtained. Such material was further purified by dissolving in water and then adding stepwise one volume, and then a second volume of Mayer's reagent<sup>5</sup>. The buff-coloured precipitates that resulted were combined and contained the bulk of salivation factor activity. Crystalline material was obtained, however, when the residual mother liquor was allowed to stand for several days at room temperature. The crystals melted with decomposition at 230°–235° C.

5.5 mg of such crystals was suspended in water and hydrogen sulphide passed through the suspension until no further precipitation occurred. HgS was removed by centrifugation and excess hydrogen sulphide removed by aeration. An aliquot of this solution when chromatographed on paper in the solvent system previously described gave a single Dragendorff positive spot,  $R_F = 0.25$ . A second aliquot of this solution, equivalent to 0.5 mg original crystalline material, gave a rating of 3 in the salivation factor assay in guinea-pigs.

The parasympathomimetic action of salivation factor suggests that it may be an anticholinesterase or an acetylcholine-like substance. Its action in this respect is very much like those of physostigmine or pilocarpine, and is reversed by atropine. Salivation factor can be distinguished from these latter alkaloids, however, by paper chromatography and other chemical criteria. *In vitro* experiments have failed to show anticholinesterase activity. Experiments are being carried out to determine the chemical nature of the salivation factor together with its mode of action.

## Factors affecting the Stimulation of Fungal Development in the Root Region

OVER recent years a justifiably large amount of attention has been directed to the role of root exudates in the stimulation of microbial development in the root region. There is, however, the possibility that the importance of exudates in this stimulation has been exaggerated and that some micro-organisms could be stimulated by the mere presence in the soil of a solid structure such as a root. With this possibility in mind, a comparison in colonization was made using live and dead roots and inert solid material (nylon thread) placed in the same soil.

(a) *Live roots.* Barley grains were planted in soil from the University of Liverpool Botanic Garden and grown for 10 days. Roots were taken from the young plants at 2, 5 and 10 days after germination of the grain, and were subjected to serial washing with sterile water (20 washings). Segments of washed root, 2 mm long, were then plated out on to Czapek-Dox + yeast extract agar (pH 5.0). The plates were kept at room temperature, and fungi developing from the plated root segments were isolated and identified.

(b) *Dead roots.* Fresh barley roots were killed with propylene oxide, and pieces 4 cm in length were buried in soil obtained from the Botanic Garden. Samples of the buried dead roots were taken 2, 5 and 10 days after burial, and fungi were isolated from washed root segments, as in the case of the live roots.

(c) *Nylon thread.* 4 cm pieces of thoroughly washed nylon thread (4 cm long and of approximately similar diameter to barley roots) were buried in the Botanic Garden soil, and sampled 2, 5 and 17 days after burial. Fungi were isolated from the pieces of thread as was done with the roots.

The results of the isolation of fungi from the three types of buried substrate are presented in Table 1; they show that for live roots the typical pattern of colonization occurs with *Fusarium oxysporum*, *Cylindrocarpum radiculicola*, *Penicillium lilacinum* and sterile dark forms being prominent colonizers. For dead roots, colonization appears to occur much more quickly (80 per cent of the plated root material yielding fungi after 2 days as compared with 60 per cent of the live root material) and by a wider range of species (14 species, as compared with 6 from live roots after 2 days), of which typical 'root surface fungi' were well represented; however, as colonization proceeded *Trichoderma viride* assumed dominance over *Fusarium* spp. and *Mortierella* spp. Sterile dark fungi, important initial colonizers of live barley roots, never

played an important part in the colonization of dead roots and quickly died out. The results obtained by plating segments of washed nylon thread showed a very marked contrast to those obtained using live and dead roots (Table 2). Here the substrate was inert and any stimulation of the soil mycoflora was caused merely by the physical presence of the thread and not by the presence of any organic materials (that is, root exudates, sloughed-off root cells, materials diffusing from the dead root material). Throughout the period of burial, colonization was extremely sparse, and because of the paucity of fungal development the final sampling time was delayed until 17 days after burial. Even after 17 days the fungi isolated were species typical of the soil rather than of the root surface (*F. oxysporum* being the only root surface form isolated—at 2 per cent frequency).

As the nylon thread was very smooth it could have been that the paucity of fungal colonization recorded was due to the fact that most of the hyphae had been removed from the thread during the washing process. However, isolations from the water used in each of the serial washings of nylon thread, which had been buried in soil for 17 days, yielded only small amounts of the 'root surface' species (that is, *Fusarium* spp.); sterile mycelia, *Cylindrocarpum* spp., etc., were not isolated. These data do not support the suggestion that typical root surface fungi develop on the nylon thread but are removed in the washing procedure.

The results obtained from plated nylon thread indicate how marked is the stimulation of soil micro-organisms by live and dead roots, and that this stimulation (or removal of fungistatic factors) is mainly due to nutrient materials supplied to the soil—the effect of their physical presence being negligible (even after 17 days burial there was little evidence of stimulated fungal development on the nylon thread).

It is interesting to compare these results with those obtained by numerous workers applying the Rossi-Cholodny buried-slide technique. These slides often show the development on their surface of complex branching hyphal systems, the development of which is thought to take place because of the physical presence of the glass slide in the soil offsetting the effects of fungistasis. It may be that the small size of the nylon thread used here allowed rapid equilibration with the soil environment (for example, the temperature might quickly have adjusted to that of the soil so that less water condensed on the thread and hence the fungistatic activity of the soil was little affected). However, the nylon threads were of much the same dimensions as the barley roots used, and therefore the physical effects of the substrates examined may be compared.

The living and dead roots are examples of organic substrates which, when added to the soil, stimulate the micro-organisms in their immediate vicinity; living roots, however, support a different mycoflora from that of dead roots. Obviously factors, such as exudates, CO<sub>2</sub> concentrations, etc., intimately associated with living roots are

of prime importance in the development of fungi on root surfaces.

## ENTOMOLOGY

### Persistence of *Erwinia amylovora* in the Apple Aphid (*Aphis pomi* DeGeer), a Probable Vector

INSECTS of the family Aphidae and particularly the apple aphid, *Aphis pomi* DeGeer, have long been suspect as significant vectors of the phyto-bacterial pathogen *Erwinia amylovora* (Burrill) Winslow *et al.*, 1920. That these insects could artificially transmit the fireblight bacterium and establish progressive infections in apple and pear tissue was demonstrated by Stewart<sup>1</sup>, Stewart and Leonard<sup>2</sup>, and Merrill<sup>3</sup>.

It was, however, not known how soon after feeding, or for how long, the pathogen could be detected within the insect. These questions remained unanswered because feeding the apple aphid *in vitro* was, until recently, an all but impossible task.

Recently in our laboratory, and independently by Mittler and Dadd<sup>4</sup> and Strong<sup>5</sup>, a system has been developed by which aphids can be successfully fed a synthetic substrate through an artificial membrane. Our simple glass feeding chamber is shown in Fig. 1 and is essentially two 3-in. pieces of glass tubing 4 mm in diameter, separated by a thinly stretched membrane of 'Parafilm-M' (Marathon Co., Menasha, Wisconsin). The Parafilm was secured with a rubber band and one of the glass tubes was drawn slightly smaller in diameter than the other so that the smaller one could be inserted into the larger.

The aphids were placed on one side of the membrane and a droplet of sap expressed from young shoots, containing a suspension of the fireblight bacterium, was placed on the other side. Active feeding by the aphid through the membrane is shown in Fig. 2. During the feeding period, the tubes were inverted so that the insect adopted approximately its normal feeding attitude on the under side of the apple or pear leaf. Furthermore, feeding in this manner prevented the dropping of ingested bacteria to the membrane surface in aphid excrement, and reduced the likelihood of contaminating the external surface of the insect.

To obviate the necessity for aseptic procedures, a virulent strain of *E. amylovora* was developed that was resistant to 1,000 µg/ml. streptomycin. The use of this genetically marked mutant permitted ready separation of *E. amylovora* from the endogenous bacterial flora of the aphid as well as atmospheric contaminants.

In replicate experiments, ten single aphids were fed the apple juice-bacteria mixture for intervals of active feeding ranging from 5 min to 2 h. In another experiment, three groups of insects fed for 2 h were placed on vigorously-growing apple shoots. The insects were subsequently removed from their natural host at intervals, and macerated in streptomycin-containing broth which was plated on streptomycin-containing agar.

The results from these experiments appear in Tables 1 and 2. They reveal that the pathogen could be found in

Fig. 1. Insect feeding chamber. A, assembled; B, unassembled

Fig. 2. Aphid actively feeding through a 'Parafilm-M' membrane

the bodies of the insects after as short a feeding period as 5 min. Moreover, the bacteria persisted in the aphid for at least 72 h, the duration of the longest experiment.

To determine whether or not contamination of the external surface of the membrane had occurred as a result of feeding, this surface, on which the aphids had rested, was swabbed with cotton and promptly streaked over the streptomycin-containing agar. In no instance was the pathogen recovered from the surface of the membrane. Hence, it would appear that our isolation of *E. amylovora* from *Aphis pomi* was, in fact, bacteria that had been ingested by the insect.

Experiments are now in progress to determine the distribution of the pathogen in the internal organs of the aphids and the approximate number of bacterial cells required to establish a progressive infection by *Aphis pomi* in host tissue.

### Pore Canals in the Cuticle of *Hypoderma bovis* (Diptera)

THE pore canals of the larval cuticle of *Hypoderma bovis* are extremely conspicuous. When the cuticle is treated with saturated potassium hydroxide solution followed by iodine and sulphuric acid<sup>1</sup>, they are seen to be occupied by helical strands of chitosan 2–3 $\mu$  thick, which give a much stronger reaction than the remainder of the cuticle. The helical nature of the canals is readily seen in a horizontal optical section. On changing the plane of focus the optical section of the canal clearly described a circular path. The diameter of the helix is about 5 $\mu$  and in vertical sections its pitch is seen to be about 6 $\mu$ . There is no relation between the pitch of the helix and the spacing of the laminae of the cuticle. Between 5 and 6 laminae are transversed by one complete turn of the helix (Fig. 1).

In electron microscope investigations on the pore canals of *Tenebrio*, *Calpodes*, *Galleria* and the honey bee, Locke<sup>2</sup> found a correspondence between the pitch of an apparent helix and the spacing of the laminae, and since the distribution of the canals in tangential section did not conform to the pattern expected for a random distribution of helical pore canals he concluded that the canals are not in fact helical, but pursue an undulating course from lamina to lamina. It is interesting, however, that the pattern seen by Locke in tangential sections resembles that seen by Drach<sup>3</sup> in similar sections of the cuticle of the crab *Carcinides* in which, as in *Hypoderma*, the canals appeared to be helical, rotating as the plane of horizontal section was changed.

Fig. 1. The pore canals of *Hypoderma bovis* as seen after the chitosan reaction

These observations on the very large and readily observed canals of *Hypoderma* are clearly in agreement with the opinion that the arthropod pore canal is helical<sup>4</sup>, and contrast with the condition reported by Locke in the insects he examined.

I thank Prof. E. A. Vincent for the photograph of the pore canals and Mr. J. C. Wood for living *Hypoderma* larvae.

### CYTOLOGY

#### Glutaric Acid Dialdehyde; a Routine Fixative for Central Nervous System Electron Microscopy

THE central nervous system of mammals presents special problems to the electron microscopist, because of its relative inaccessibility, and the fact that the brain is by no means a uniform organ but is composed of sub-units, about the structure or function of which we know little, and because of the extremely soft nature of fresh cerebral tissue. Although the most accessible area, the cerebral cortex, has been investigated extensively, it still remains to investigate the less superficial sub-units in detail. Attempts to dissect out such deeper structures from slices of soft, fresh brain, and then to cut these into smaller pieces for adequate fixation in osmium tetroxide, are often attended by disruption of structural organization resulting largely from mechanical manipulation—dark neurones are familiar to both light and electron microscopists.

The slow penetration of buffered osmium tetroxide during the first 2 h results in only superficial fixation when thin coronal slices of fresh brain are completely immersed in solutions of the fixative. The reduction of osmium tetroxide during fixation produces a diffuse blackening of these slices, so that all detail of deeper structures—the contrast between grey and white matter so important in gross anatomical localization—is obscured. Likewise, attempts to fix the central nervous system *in situ* by perfusing osmium tetroxide through the vascular system produce excellent tissue preservation in skilled hands<sup>1</sup>, but again, due to diffuse blackening of the fixed organ, specific anatomical localization cannot be readily performed.

Osmium tetroxide, though an excellent fixative, destroys enzymatic activity very quickly, and for this reason less-destructive fixatives such as formalin, acrolein and glutaric acid dialdehyde<sup>2–4</sup> have been introduced in an attempt to preserve fine tissue structure as well as enzymatic activity. We have found that glutaric acid dialdehyde (glutaraldehyde) used as a routine primary fixing agent for the central nervous system, followed by post-fixation in osmium tetroxide, gives very adequate fine structural preservation of whole coronal slices of the brain of the mouse and the Syrian hamster.

We have used a 6.5 per cent solution of glutaraldehyde buffered at pH 7.4 with either 0.1 M phosphate or 0.1 M cacodylate buffer, though the phosphate buffer (Sorensen) has been found to be the most stable. Excellent tissue preservation was obtained both by perfusion via the left ventricle and ascending aorta, and by immersion of whole coronal slices, 2–4 mm in thickness, in buffered glutaraldehyde. We prefer the immersion method, because the majority of small vessels are greatly distended by perfusion, making their structure and their relationship to the neighbouring parenchyma difficult to interpret.

Fixation was allowed to proceed for 1.5 h at 4° C, then the coronal slices, after preliminary washing in 0.2 M sucrose in either 0.1 M phosphate or 0.1 M cacodylate buffer at pH 7.4, were examined under a dissecting microscope. Glutaraldehyde caused a slight yellowing of all brain areas, but did not interfere with gross anatomical localization. Small blocks could then be removed at leisure with a sharp razor blade from any selected area, and shaped for later orientation when embedding. The selected blocks were then washed further in the sucrose phosphate or sucrose cacodylate buffer for 24–48 h before post-fixation for 1.5 h at 4° C in 1 per cent osmium tetroxide buffered in veronal acetate. We have used Vestopal 'W' as an embedding medium, but other plastics—'Araldite' and 'Epon', etc.—may also be used. However, as indicated by Sabatini *et al.*<sup>4</sup>, mixtures of methyl and butyl methacrylate were not suitable, as extensive sublimation

## SOIL SCIENCE

## Dispersion of Mineral Colloids in Soils using Cation Exchange Resins

THE techniques for particle size distribution analysis of soils which have gained general acceptance are those which include a pre-treatment with an oxidizing agent such as hydrogen peroxide<sup>1</sup> or sodium hypobromite<sup>2</sup> to destroy, as completely as possible, the organic materials present. It is customary also, where hydrogen peroxide has been used, to add a peptizing or dispersing agent, usually in the form of a soluble salt such as sodium metaphosphate<sup>3</sup>, before the oxidized soil material is shaken in water suspension to obtain separation of the mineral particles. However, for a realistic investigation of the processes of dispersion and aggregation in soils, a method is required which results in complete separation of the mineral particles without the destruction or irreversible alteration of any organic materials present and without degradation of the mineral colloids<sup>4</sup>. These requirements preclude the use of bases or soluble salts, since those which are efficient dispersing agents invariably dissolve soil constituents, and the materials solubilized can be lost from the system along with the added chemicals if desalting is attempted. These stringent requirements led to the development of the method of dispersion described here.

Dispersion with cation exchange resins was accomplished by shaking 10 g of < 2 mm soil in 60 ml. of de-ionized water with an amount of any one of the three major types of synthetic cation exchangers (iminodiacetic, carboxylic or sulphonate acid resins, arranged in order of decreasing speed of dispersion) sufficient to supply 15 m.equiv. of a monovalent cation such as Na<sup>+</sup>, K<sup>+</sup> or NH<sub>4</sub><sup>+</sup>. Shaking was carried out in 100-ml. cylindrical, wide-mouthed, screw-topped bottles of pliable polyethylene to minimize mechanical abrasion, and an equipoise shaker, with a 'sponge' rubber-lined box, was used at a regulated voltage. The time required to obtain maximum dispersion varied, not only with the type of resin used, but also with the cation saturation, bead size, surface area and hardness of the various resins and also with the soil material being dispersed. Soils high in both montmorillonite clay and organic matter were most difficult to disperse, and, with these, a clay-percentage plateau was reached, using 16-50 mesh sodium-saturated resins, in 2 h with 'Dowex A-1' (iminodiacetic acid structure), 10 h with 'Amberlite IRC-50' (carboxylic acid structure) and 20 h with 'Amberlite IR-120' (a sulphonate acid resin). However, the shaking time required using 'Amberlite 200', a sulphonate acid exchanger with a mechanically stable macroreticular structure and relatively large surface area compared with the gel matrix of the 'Amberlite IR-120', was comparable with that necessary for maximum dispersion using 'Amberlite IRC-50' (10 h).

The foregoing dispersion technique was designed initially to serve as a pretreatment for particle size distribution analysis by the pipette method. For this purpose the soil-water-resin mixtures were transferred, following shaking, directly to 1-l. glass cylinders. This practice was adopted after establishing, for a wide range of soils, that removing the resin and sand in the process of making the suspensions up to volume for sedimentation gave results, for percentages of silt and clay, identical to those achieved with the coarse materials present. Following sedimentation and the removal of aliquots of silt plus clay and clay, the resin (normally in the 16-50 mesh size range) was separated from the finer sand fractions by sieving and from the coarser sands and gravel by flotation in a stream of water. The dissolved organic materials present in the silt plus clay and clay aliquots, and the small amounts of insoluble plant residues remaining with the sand fractions, were destroyed before weighing by treatment with 3 per cent hydrogen peroxide (5 ml. of 30 per cent added to 50 ml. of water or suspension).

Fig. 1. Well-preserved Palade granules, granular (ER) and agranular (G) endoplasmic reticulum and mitochondria (M) occupy the cytoplasm of a Purkinje cell. ( $\times 15,000$ )

Fig. 2. All available space between myelinated axons (Ax) in the brain stem is occupied by closely apposed cell processes. ( $\times 15,000$ )

of the ultrathin sections occurred in the electron beam, grossly distorting the fine structure.

Neurons and glial cells from the cortex, hippocampus, thalamus, cerebellum (Fig. 1) and brain stem were uniformly preserved. The spaces between the apposed filaments of the granular endoplasmic reticulum were slightly wider than those observed with tissue fixed in osmium tetroxide alone, and they enclosed an amorphous material. There was neither undue mitochondrial swelling nor clumping of cell cytoplasm. The grey and white matter (Fig. 2) showed no large extracellular spaces either in the parenchyma or around capillaries, although appreciable spaces did appear between cell processes in the region of the area postrema.

These observations suggest that glutaraldehyde may be extremely useful, not only for the preservation of fine structure for enzymatic investigations, but as a routine fixative for the preservation of the central nervous system for both anatomical and pathological electron microscopic examination.

<sup>4</sup> Sabatini, D. D., Bensch, K., and Barnett, R. J., *J. Cell Biol.*, **17**, 19 (1963).

Separation of the sand and resin was not required where 'Amberlite 200' was used, because of the mechanical stability of the resin and its resistance to oxidation in 3 per cent hydrogen peroxide.

In the absence of any absolute standard of dispersion, the cation exchange resin technique was compared, on a wide range of surface and sub-soil materials from the United States, Canada and Australia, with the results from the procedures found to yield the highest clay percentages in a recent investigation by Protz and St. Arnaud<sup>5</sup>. The most effective of these was a method based on the work of Troell<sup>2</sup> in which sodium hypobromite was used as an oxidant. The cation exchange resins (sodium saturated) gave clay percentages which compared favourably with those from the hypobromite procedure applied to the same soils. The reproducibility of size distribution analyses carried out on resin-dispersed suspensions has also been excellent. For example, the percentage of <2 $\mu$  material in a Nicollet soil from Iowa, based on mechanical analyses of 6 separate 10-g samples, was shown to be  $23.26 \pm 0.25$ .

The soils effectively dispersed using the cation exchange resin technique have been grassland and forest soils with high base status in which aggregation is due largely to the presence of a clay-organic matter complex. The maximum dispersion of mineral colloids in such soils has been achieved coincident with a high degree of dissolution of soluble organic materials. The dispersion procedure described here was therefore used as the initial step in a method for the extraction of humus, the next step being the removal of the sand and resin by sieving. The silt and part of the clay-sized mineral fraction were then removed, largely free of organic matter, by sedimentation in a 2-l. separatory funnel having a stopcock fitted with a large-bore 'Teflon' plug for bottom withdrawal of the sediment. The small volume of suspension removed with the sediment was collected in a plastic suction filter funnel fitted with a 'Millipore' or 'Polypore' filter paper with pores about 0.3 $\mu$  in diameter. To minimize re-formation of a clay-organic matter complex during filtration, a few grams of a finely divided (200-400 mesh) sodium-saturated cation resin such as 'Amberlite IRC-50' were added to the funnel prior to the application of suction. When sedimentation had essentially ceased, the filtrate was returned to the bulk of the extract. The resulting solution-suspension contained, in essentially unaltered form, most of the humified organic materials, along with finely divided and highly dispersed clay minerals. The latter could not be completely removed by centrifuging or filtering without loss of some of the organic materials of higher molecular weight, but the possibility of destroying the silicate minerals in the extract with a mild hydrofluoric acid treatment is being investigated.

The only modification of the dispersion procedure required to carry out investigations on the process of soil aggregation was a preliminary grinding of the soil samples to permit separation of the resin from the whole soil following dispersion. This separation was made by sieving, under suction, using small stainless steel screens in plastic mounts which were fitted into Buchner funnels with rubber rings. After washing several times with small volumes of de-ionized water, the suspensions were evaporated down at room temperature by using a stream of air from a hot-air drier. Stirring to obtain uniform distribution of the dissolved organic matter was necessary when the paste stage was reached. When dried to original moisture content, the soil samples were crushed to their original state (to pass a 2-mm sieve) and were then subjected to particle-size distribution analysis following partial dispersion of 10-g samples by shaking in 60 ml. of de-ionized water for 10 h. The results were compared with those obtained on samples of the original soils shaken in water in the same manner. The analyses showed that, even with the exchange complex partially saturated with monovalent ions, the soils dispersed and

then air-dried contained almost the same proportions of stable aggregates as were present originally. The effects of restoring different di- and poly-valent cations were also examined using suitably saturated cation exchange resins which were added and removed before the drying step.

The use of cation exchange resins as dispersing agents and extractants of soluble organic matter has shown clearly that the polyvalent metal ions known to complex organic materials in soils into insoluble forms<sup>6</sup> also are involved in formation of micro-aggregates which include clay minerals. Contact exchange of monovalent ions on the resins for some of these polyvalent ions in the clay-polyvalent metal ion-soil organic matter complex, achieved by shaking a mixture of soil and resin in water suspension, results in both dispersion of the clay fraction and dissolution of that portion of the humus which is potentially water-soluble.

## GENETICS

### Serum Albumin and Transferrin Polymorphism in East African Cattle

A SURVEY of the serum proteins of several breeds of East African cattle by starch-gel electrophoresis has recently been carried out. During this survey, a new transferrin phenotype was seen and a previously undescribed variation in the serum albumin, presumably representing serum albumin polymorphism, was found.

The starch-gel procedure used was essentially that described by Ashton and Braden<sup>1</sup> for mice serum proteins and by Ashton and Ferguson<sup>2</sup> for sheep. In this system the electrolyte was composed of 2.2 g lithium hydroxide monohydrate (53-55 per cent LiOH) and 11.8 g boric acid per litre of solution. The gel was prepared from hydrolysed starch (Connaught Laboratories, Toronto, Canada) at the recommended strength, and the buffer consisted of 450 ml. of a solution containing 1.6 g *tris* (hydroxymethyl)-aminomethane, and 7.8 g citric acid per litre, to which was added 50 ml. of the electrolyte. The hot gel solution was poured into a tray containing six adjacent compartments, each 0.3 × 4 × 25 cm internally, and the electrolyte was connected to the gel by a thin plastic sponge (Wettex, Aust. Pty., Ltd., Sydney, Australia) which overlapped the gel by 4 cm at either end. The samples were inserted 8 cm from the cathode end of the gel, on very thin filter paper (Ekvip Industrial Equipment Pty., Ltd., Sydney, Australia). Either three or four samples per compartment were inserted, one a reference sample, and the gel was covered with polythene film to avoid evaporation during electrophoresis.

With this system, when an initial current of 100 mA per gel was passed, optimal resolution was obtained after about 2 h. The albumin zone, which should be narrow (2-3 mm), had then migrated about 9-10 cm, and the brown zone of discontinuity about 13-14 cm. This system gives excellent resolution of transferrin, post-albumin<sup>3</sup>, and albumin polymorphism<sup>4</sup>.

The serum samples examined were from Boran, Sahiwal, Nganda, Teso, Ankole and Tanganyika shorthorned Zebu cattle. Full details of the gene frequencies and other information will be reported elsewhere. From the total

Fig. 1. Photograph and corresponding diagram of a gel carrying three serum samples, showing (left to right) transferrin types B/E, G/F and B/B. The diagram also shows the expected position of the postulated homozygote G/G, and the relative position of an A/A phenotype. Alb, albumin; p.a., post-albumins; Tf, transferrins; Sa, slow- $\alpha$  globulins.

of about 1,100 samples representing the different types of cattle, three Borans out of a group of approximately 300 from the East African Veterinary Research Organization. Genetics herd showed a previously undescribed transferrin phenotype (Fig. 1). The three animals showing this type were members of the same family, and it seems probable that they represent the heterozygote of  $Tf^{FF}$  (ref. 5) and a 'new' allele which, following the pattern previously adopted<sup>2,3</sup>, will be coded provisionally with the next available letter,  $Tf^G$ . The new phenotype is accordingly  $Tf^{G/F}$ . The heterozygote  $Tf^{G/G}$  will presumably show the usual four zones<sup>6</sup>, and the slowest of these will align with the second fastest zone of  $Tf^{A/A}$  (Fig. 1). The phenotypes of other heterozygotes of  $Tf^G$  may be forecast by the diagrammatic approach used for  $Tf^{B}$  and  $Tf^{F}$  in Zebu cattle<sup>5</sup>.

Serum albumin polymorphism is shown in Fig. 2. Although it can be detected in the described system in gels with undiluted serum samples inserted, it is revealed more readily when the serum is diluted to one part in six with water before electrophoresis. Five albumin phenotypes have been recognized, three of which appear to be

common and two rare. The three common types have been coded A, AB and B, and the two rarer types AC and BC (Fig. 2). The three common types occurred in all the breeds examined, but the two rarer types were found only in the Tanganyika shorthorned Zebu. However, only the latter and the Ankole samples were examined in detail for albumin polymorphism, and the presence of the AB and C phenotypes in the other breeds is not excluded.

The 74 Ankole sera which were examined in detail included 17 A, 29 AB and 28 B phenotypes, and among 83 Tanganyika shorthorned Zebu sera there were 16 A, 25 AB and 42 B types. In both breeds the distribution of phenotypes was compatible with Hardy-Weinberg distribution for a two-allele, three-genotype system. It seems probable that the albumin variants described reflect serum albumin polymorphism. It is therefore proposed that the locus symbol for this system is  $Alb$  and the two common alleles,  $Alb^A$  and  $Alb^B$ . The three common phenotypes found may then prove to be  $Alb^{A/A}$ ,  $Alb^{A/B}$ , and  $Alb^{B/B}$ . The two rarer phenotypes BC and AC may represent the products of  $Alb^A$  and  $Alb^B$ , with a third allele,  $Alb^C$ . So far, no mating data are available to test this hypothesis. European and other breeds of cattle are to be examined for this polymorphism.

McIndoe<sup>7</sup> has described serum albumin polymorphism in the domestic fowl. Two serum albumins have also been described in some of the members of a few human families. Serum albumin polymorphism may well be a widespread phenomenon.

We thank the director and staff of the East African Veterinary Research Organization for facilities and for the collection of samples.

## VIROLOGY

### Behaviour of an Attenuated Strain of Foot-and-mouth Disease Virus in Culture

In previous articles<sup>1,2</sup> it was reported that differences were found between virulent and attenuated strains of foot-and-mouth disease virus in surviving cultures of calf tongue epithelium. The attenuated strains (a) gave rise to a lower number of infective centres after adsorption, (b) were less efficiently titrated in the epithelial cultures, (c) multiplied to a lower titre, but (d) produced more interferon, and (e) were more sensitive to interferon action than the virulent strains. From the findings it was suggested that at the most only 5 per cent of the attenuated strain was competent, that is, was able to initiate infection and the further production of virus. The other 95 per cent was thought to enter the cell, inducing cellular resistance and the production of interferon. As a result of successive multiplication cycles of competent virus there was a build-up of non-competent virus and of interferon, which, in turn, inhibited the growth of competent virus. Hence there was a failure of lesion development in animals but still sufficient antigen production to stimulate immunity.

Fig. 2. Photograph and corresponding diagram (centre) of the albumin region of a gel carrying three diluted serum samples, showing (left to right) the albumin phenotypes AC, AB and BC. The lower diagram shows the three common phenotypes A, AB and B.

It was decided to investigate the behaviour of the attenuated strain after repeated passage in the calf tongue epithelial cells, for which the strain before attenuation had been fully virulent. In addition actinomycin D, which had been shown to block the production of interferon<sup>3-5</sup>, was investigated for its effect on the production of competent and non-competent virus and of interferon.

Virus of Venezuelan strain, type 'O', after 95 passages in 1-day-old chicks, six passages in 9-day-old chick embryos<sup>6</sup> and four passages in BHK 21 cells<sup>7</sup>, was used as the attenuated strain (ATT VI BHK 4). The virus of the first BHK 21 cell passage was passaged in surviving calf tongue epithelial cells (BTE cells) and used as the 10th passage (ATT VI BHK 1 BTE 10). BTE tube cultures were infected with about  $10^4$ – $10^{4.6}$  mouse ID<sub>50</sub> of virus. Actinomycin D (kindly supplied as 'Lyovac' 'Cosmogen' (Meractinomycin) by Dr. R. A. Pingeon of Merck, Sharp and Dohme Research Laboratories, New York) was added to one group of cultures at a concentration of 0.06 µg/ml. and was left in the culture throughout the experiment. The cultures were incubated at 37° C and three tubes were collected daily. The contents were pooled, and the supernatant fluid divided into two parts. One part was tested for virus content by inoculation of unweaned mice and, for comparison, of BTE cultures<sup>2</sup>. The other part was treated with acid and tested for interferon content in BTE cells<sup>1-2</sup>.

Table 1. TITRES OF VIRUS AND INTERFERON PRODUCED AFTER INOCULATION OF SURVIVING CALF TONGUE EPITHELIAL CULTURES

Virus strain	Treatment		Day	Day	Day	Day
			1	2	3	4
O ATT VI BHK 4	Nil	V*	6.3	5.6	5.0	4.2
		I†	0.0	1.8	3.0	3.0
O ATT VI BHK 4	Actinomycin D 0.06 µg/ml.	V	7.0	5.5	5.0	4.1
		I	0.0	0.0	0.2	0.0
O ATT VI BHK 1 BTE 10	Nil	V	5.1	6.3	5.6	6.25
		I	0.0	0.0	0.1	0.2

\* Virus titre expressed as log<sub>10</sub> mouse ID<sub>50</sub>/ml.

† Interferon titre expressed as log<sub>10</sub> VSV production in control minus log<sub>10</sub> VSV production in interferon-treated cultures.

The results of one experiment are shown in Table 1. It can be seen that in the ATT VI BHK 4 actinomycin D-treated cultures there was more virus on the first day than in the untreated ATT VI BHK 4 cultures, but this was not found in every experiment. With the passaged strain (ATT VI BHK 1 BTE 10) virus production was delayed, but titres reached were of the same order and in some experiments higher than those of the original attenuated strain. A constant feature of all experiments was that little or no measurable interferon was detected in cultures treated with actinomycin D or in cultures infected with the BTE-passaged virus. However, in these cultures the composition of the virus population which was produced remained similar to that of the original strain. In Table 2 the results of comparative titrations in unweaned mice and BTE cells are shown, and from this and other comparative titrations it was demonstrated that the log difference between the titres in mice and BTE cells was of the same order and the virus populations in all three instances consisted of about 1 per cent competent virus and 99 per cent non-competent virus.

Table 2. COMPARATIVE TITRES IN UNWEANED MICE AND IN TONGUE EPITHELIAL CULTURES

Virus strain	Previous treatment	Mouse log	BTE log	Log
		ID <sub>50</sub> /ml. (a)	TCD <sub>50</sub> /ml. (b)	difference (a-b)
O ATT VI BHK 4 BTE 1	Nil	5.4	3.1	2.3
O ATT VI BHK 4 BTE 1	Actinomycin D	4.75	2.5	2.25
O ATT VI BHK 1 BTE 11	Nil	5.9	3.5	2.4

The finding that interferon production was inhibited by actinomycin D confirms the results of other workers<sup>3-5</sup>. No change, however, was noted in the virus population produced, which with 1 per cent competent and 99 per cent non-competent was the same as that produced by the attenuated strain without treatment. This confirms that actinomycin D probably has a direct effect on a cellular

mechanism involved in interferon production<sup>3,4</sup>. The finding that the virus passaged 10 times in BTE cells gave results similar to those obtained in actinomycin D-treated cultures can be interpreted by assuming a change in virus nucleic acid composition during passage. The virus after passage probably contained calf-cell-synthesized components in its nucleic acid. It no longer appeared to the cell as foreign nucleic acid<sup>8</sup>, and thus did not set off the cellular mechanism for interferon production.

Lack of virulence on the part of the attenuated strain appears to be due to at least two factors. First, the virus population consists of 1–5 per cent infective or competent virus and 95–99 per cent non-infective or non-competent virus in contrast to the virulent strain, which has been shown to consist of 50 per cent or more competent virus<sup>2</sup>. Secondly, the cell reacts to the introduction of foreign nucleic acid by the attenuated strain with the production of interferon, which inhibits in turn further infection by competent virus. Actinomycin D and passage in BTE cultures abolished or reduced the second factor, but the first factor was unaltered. To what extent the virulence for cattle as compared with virulence in BTE cultures was regained by these treatments must await tests in susceptible cattle.

## Electron Microscopy of a Tick-borne Encephalitis Virus

CLARKE<sup>1</sup> showed that a strain of tick-borne encephalitis virus, 'A52', isolated in Finland<sup>2</sup>, is antigenically identical with the Central European tick-borne encephalitis viruses. Sokol *et al.*<sup>3</sup> reported that the particles of the 'Hypr' strain of Central European tick-borne encephalitis virus purified from mouse brain suspension were predominantly spherical, and about 30 mµ in size. The same strain in HeLa cells has been demonstrated to be round-shaped with a dense inner body and a transparent outer zone surrounded by a surface membrane<sup>4</sup>. In the present work the negative staining technique<sup>5</sup> was used to determine the size and shape of particles of the strain 'A52', grown in tissue culture.

Monolayer cultures of a continuous line of human amnion cells<sup>6</sup> were inoculated with a virus grown in mouse brain at a multiplicity of approximately one mouse infectious dose per cell. After two weeks incubation at +37° C, virus was collected, clarified from cell debris by centrifugation at low speed and concentrated ten times in 'Cellophane' tubes by evaporation at room temperature for 30 h. The preparation with its high salt content was dialysed against phosphate-buffered saline, pH 7.4, overnight at +4° C. After 5 days storage at +4° C, 10 ml. of the preparation was diluted 1 to 5 with 1 per cent ammonium acetate containing 0.1 per cent bovine albumin (Armour, Fraction V). The pH of the diluent was adjusted to 7.3 with 1 N potassium hydroxide. The diluted preparation was centrifuged in a Spinco Model L centrifuge at 105,000g for 2 h. Four-fifths of the supernatant from the top was discarded, and the pellet was re-suspended in the remaining part and clarified by low-speed centrifugation. The supernatant in an equal volume of diluent was re-spun at 105,000g for 100 min.

Fig. 1. Particles of a tick-borne encephalitis virus stained with PTA

Fig. 2a. Particle with a curved tail. 2b. Particle with a bud-like bulb. 2c. Two spherical particles. 2d. Particle filled with PTA

Nine-tenths of the supernatant was discarded, and the pellet was re-suspended in the remaining part. After these centrifugations the evaporated preparation was concentrated five-fold in volume but haemagglutinins were increased only four-fold. The virus, in an equal volume of 4 per cent phosphotungstic acid (PTA) containing 0.4 per cent sucrose, was sprayed on carbon-coated grids and, after air-drying, was examined with a Siemens Elmiskop I electron microscope at an original magnification of 29,000.

The particle size varied from 30  $\mu$  to 40  $\mu$ , the average being 36  $\mu$ . About one-third of the particles had tail-like projections, some of which were straight, others slightly curved (Figs. 1 and 2a). The length of the tails varied from 16  $\mu$  to 32  $\mu$ ; the width was mostly about 12  $\mu$ . In some cases the heads and tail-like projections had the same electron density, but bud-like bulbs were also seen (Fig. 2b) and were mostly less dense than the heads. The particles were mainly spherical, but angular ones, hexagonal or pentagonal, were also seen (Fig. 2c). Some of them seemed to be filled with PTA (Fig. 2d). Structures similar to those described above were not observed in uninfected tissue culture fluids prepared in the same manner as the virus preparations.

Smith and Holt<sup>7</sup>, using negative staining, demonstrated that the particles of another tick-borne encephalitis virus, strain 'TP 21' of the Langat virus, obtained from a chromatographic fraction of mouse brain material, were roughly spherical, 32–37  $\mu$  in size, and several particles appeared to have a triangular facet. Tail-like particles of an A-group arbovirus, 'WEE' virus, have previously been described by Sharp *et al.*<sup>8</sup> in unfixed preparations of the purified virus stored 16 days at +4°C.

Some recent work indicates that certain animal viruses may have a tail<sup>9–11</sup>. On the other hand, distortion in

shape may be due to the conditions of preparing the virus for electron microscopy<sup>12,13</sup>. Further investigations are required to determine whether the tail-like projections described in the present report do exist under natural conditions or if they are produced in the preparation of the virus.

We thank Prof. N. Oker-Blom, Prof. A. Telkka, and Prof. P. Halonen for advice, and Mr. M. Lehtimäki for photographic assistance.

## ARCHAEOLOGY

### Radiocarbon Dating of the Nok Culture, Northern Nigeria

AN early occupation site was located at Taruga, south-east of Abuja, in Niger Province of Northern Nigeria in November 1960, and fourteen exploratory trenches were dug by me early in January, 1961, for the Federal Department of Antiquities. Figurines characteristic of the Nok style had been found by tin miners in sample pits close by, and many other figurine fragments were afterwards excavated *in situ* together with decorated pottery, querns, quartz hammerstones, iron slag and quantities of charcoal. Four, and in some places five, distinct layers were observed in a depth of about 4 ft.

Charcoal excavated from layer three was submitted for determination to Isotopes Incorporated of Westwood, New Jersey, with the following result:

Isotopes Inc. Determination No.	Sample	Age (years B.P.)
I-1458	Sample B Taruga	2,230 ± 120

A date of 280 B.C. for an undisturbed Nok site containing abundant evidence of iron-working correlates satisfactorily with the original pre-radiocarbon date for the Nok Culture (based on geomorphological evidence) of the last four centuries B.C. The only other indisputably undisturbed wood specimen (excavated in a completely fresh condition with the bark still unscratched in the heart of the grey clay beds at Nok) gave a carbon date of 206 A.D. ± 50 years (Y 474). These two dates provide evidence of the survival of a single early iron age culture for nearly five centuries and there is at present no reason at all to believe that this did not begin earlier and survive later.
